

Appendix 2. Species list and percentage frequency of taxa according to the regional ecosystems defined in this paper

Species nomenclature follows Henderson (2002), except where authorities are provided. Exotic species are identified with a superscripted asterisk, following Henderson with the exception of *Cyrtodactylon dactylon* which is considered here as an exotic. Species occurring on Great Artesian Basin discharge spring wetlands are identified with a superscripted I, and species occurring on recharge spring wetlands with a superscripted R. A species class is provided according to Fensham and Price (2004) where endemic species (E) are only known from the wetlands of permanent springs, principal species (P) occupy the wetland habitat that is permanently inundated and are not normally known outside wetlands that are flooded for extended periods (i.e. more than 50% of the time), facultative species (F) occupy the habitat that is permanently inundated but are also known from terrestrial habitats in other parts of their species ranges, seasonal species (S) occupy the areas of the spring wetland that are only seasonally wet (hence chiefly confined to springs with fluctuating flows), aquatic species (A) occupy areas of free water where this habitat is available in large spring wetlands or where mechanical excavation has formed dams and microhabitat species (M) occur around the margins of spring wetlands where the location of a spring provides suitable microhabitat (i.e. sheltered, humid and usually rocky habitat provided around recharge springs set in gully heads on rocky ranges). Incidental species, defined by Fensham and Price (2004) as species that can occur in any particular spring wetland but have their primary habitat in the terrestrial habitats in the vicinity of that spring, are not included. The spring wetland regional ecosystems are identified by the biogeographic-region (number before the point) and land-zone codes (number after the point) (see Table 1)
