Table S1. Summary of the condition of ovarian histology slides (563 of 598 samples examined) categorised (distinct, adequate, marginal) by ease of assignment to maturity status.

| Histology <br> condition | Preservation <br> method | Maturity <br> status | $\boldsymbol{n}$ | Proportion for a given <br> preservation method and <br> maturity status |
| :--- | :--- | :--- | ---: | :---: |
| Distinct | Glyo-Fixx | Immature | 133 | 0.723 |
| Adequate | Glyo-Fixx | Immature | 33 | 0.179 |
| Marginal | Glyo-Fixx | Immature | 18 | 0.098 |
| Distinct | Formalin | Immature | 24 | 0.118 |
| Adequate | Formalin | Immature | 81 | 0.397 |
| Marginal | Formalin | Immature | 99 | 0.485 |
| Distinct | Glyo-Fixx | Mature | 27 | 0.310 |
| Adequate | Glyo-Fixx | Mature | 50 | 0.575 |
| Marginal | Glyo-Fixx | Mature | 10 | 0.115 |
| Distinct | Formalin | Mature | 27 | 0.307 |
| Adequate | Formalin | Mature | 48 | 0.545 |
| Marginal | Formalin | Mature | 13 | 0.148 |

Categories are displayed by the two preservation methods (preserved at sea in Glyo-Fixx or held frozen at sea and later preserved in $10 \%$ neutrally buffered Formalin) and by maturity status (immature and mature).

Table S2. Summary of female and male maturity ogive results based on robust logistic regression analysis across all months (total) and female spawning season only (May-July) excluding regenerating (EXREG) phase female and male samples respectively.

| Model name | $\beta_{1}$ | $\beta_{1}($ s. d. $)$ | $\beta_{1}(\mathbf{c v})$ | $P$ value | Test statistic | d.f. | Pr>ChiSq |

| ${ }^{\top} \mathrm{M} 2 . S S . E X R E G$ | 0.061 | 0.019 | 31\% | $<0.001$ | 4.03 | 195 | 0.077 |
|  | $n$ |  |  | $L_{\text {EF50 }}$ S.d. | $L_{\text {EF95 }}$ |  | $L_{\text {EF95 }}$ s.d. |
| $\chi^{\text {J M }}$ M1.Total.EXREG | 434 |  |  | 2.8 | 157.6 |  | 3.4 |
| ${ }^{\top} \mathrm{M} 2$. Total.EXREG | 434 |  |  | 9.0 | 164.7 |  | 10.0 |
| ${ }^{\top}$ M1.SS.EXREG | 199 |  |  | 10.3 | 158.6 |  | 6.7 |
| $\delta^{\top} \mathrm{M} 2 . S S . E X R E G$ | 199 |  |  | 9.4 | 170.5 |  | 10.0 |

Model names "M1" have eye-fork length (EFL) as the predictor while "M2" uses EFL and month as predictors; prefix $Q$, females; $\delta^{\lambda}$, males. Model names that include "SS" indicate analysis is restricted to the May-July female spawning season. All model runs exclude regenerating (EXREG) phase females and males. Other column heading abbreviations: $\beta_{1}=$ slope of the maturity ogive; cv, coefficient of variation; d.f., degrees of freedom; $L_{\text {EF50 }}$, length at median ( $50 \%$ ) maturity; Lef95, length at $95 \%$ maturity; $n$, sample size; na, not applicable; s.d., standard deviation. Parameter values of best fit model for each sample category displayed in bold.

Table S3. Summary of robust logistic regression model results fitted to total females sampled and females collected during the spawning (May-July) and non-spawning (August-April) seasons.

| m2.nr.fem.nsp | 324 | 339.897 | 37943.060 | 367.454 | 37943.080 | 0.107 |

Model names with "m1" have eye-fork length as the predictor and with "m2" have eye-fork length (efl) and month (as a factor) as predictors noting that the estimated month effect parameters are not shown here for brevity. Model names with "sp" are fit to data collected during the spawning season and with "nsp" are collected during the nonspawning season. Model names without "sp" or "nsp" were analysed using total females sampled.

Model 1 ( R model object code is $\mathrm{m} 1 . f e m . s p . r o b$ ) produced the best fit to the female maturity data collected during the spawning season in comparison to Model 2 ( R model object code is m 2 .fem.sp.rob) based on the Robust Wald test results.

## > anova(m1.fem.sp.rob,m2.fem.sp.rob,test="Wald")

Robust Wald Test Table
Model 1: mature ~ efl
Model 2: mature ~efl + month_F
Models fitted by method 'Mqle'

| $\underline{\text { Model }}$ | $\underline{\text { pseudoDf }}$ | $\underline{\text { Test.Stat }}$ | $\underline{\operatorname{Df}}$ | $\underline{\operatorname{Pr}(>\text { chisq })}$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| 1 | 225 |  |  |  |
| $\underline{2}$ | $\underline{223}$ | $\underline{0.56543}$ | $\underline{2}$ | $\underline{0.7537}$ |

Results for the best fitting model with all samples indicated that there was a highly significant fit to the maturity data ( $\mathrm{P}<0.0001$ ). Fish length was the only significant predictor and Model 1 produced reasonable residual patterns based on the histogram and quantilequantile ( $\mathrm{Q}-\mathrm{Q}$ ) plots of the randomised quantile residuals shown below. The estimate of the length at $50 \%$ maturity was $L_{50}=152.2 \mathrm{~cm}$ with a standard error of 1.8 . The estimate of the length at $95 \%$ maturity was $\mathrm{L}_{95}=166.6 \mathrm{~cm}$ with a standard error of 2.2 . The estimate of the slope of the maturity ogive was $\beta_{1}=0.204$ with a standard error of 0.034 (Table S3). A summary of the best fitting model with all samples is listed below along with the predicted dose responses. The histogram and Q-Q plot of the quantile residuals is shown in Fig. S1 and S2 respectively.

$1 \quad 179$
$\underline{2} \quad \underline{177} \quad \underline{0.25113} \quad \underline{2} \quad \underline{0.882}$
Results for the best fitting model with all non-regenerating spawning season samples indicated that there was a highly significant fit to the maturity data ( $\mathrm{P}<0.0001$ ). Fish length was the single significant predictor and Model 1 produced adequate residual patterns based on the histogram and Q-Q plots of the randomised quantile residuals shown above (Fig. S3 and S4 respectively). The estimate of the length at $50 \%$ maturity was $\mathrm{L}_{50}=153.6 \mathrm{~cm}$ with a standard error of 1.9. The estimate of the length at $95 \%$ maturity was $\mathrm{L} 95=170.9 \mathrm{~cm}$ with a standard error of 2.7. The estimate of the slope of the maturity ogive was $\beta_{1}=0.170$ with a standard error of 0.028 (Table S4). A summary of the best fitting model with all non-regenerating spawning season samples is listed below along with the predicted dose responses. The histogram and Q-Q plot of the quantile residuals is shown in Fig. S3 and S4 respectively.

(a)

Fig. S5. Female length density distribution plots of striped marlin lengths (eye-fork length, cm ) measured and sampled for subsequent gonad histology by domestic longline observers onboard vessels of the Hawaii-based pelagic longline fleet fishing in the central North Pacific. Plots displayed are based on sampled females (excluding regenerating phase females) that represent (a) total females ( $n=505$ ), (b) total immature females ( $n=394$ ), (c) total mature females $(n=111),(d)$ spawning season females $(n=181),(e)$ spawning season immature females $(n=82)$, ( $f$ ) spawning season mature females ( $n=99$ ), ( $g$ ) non-spawning season females $(n=324)$, ( $h$ ) non-spawning season immature females $(n=312)$, $(i)$ non-spawning season mature females ( $n=12$ ).
