An Abnormal Clutch of Blue-faced Honey Eater's Eggs
(*Entomyza cyanotis harterti*)

Clutch of seven eggs taken by W. McLennan at Coen, Cape York Peninsula, North Queensland, on 3rd April, 1922. In his notes W. McLennan says:—

"Flushed a Honey-Eater (*E. cyanotis*) from a Babbler's nest, 10 feet from ground in a Swamp Paperbark tree (*Melaleuca*); it contained a remarkable set of seven eggs. The Babbler's nest was quite a fresh one; the Honey-eaters evidently took possession before it was fully lined, as the strips of paper-bark used by the Honey-eaters were mixed with the strips of messmate bark used by the Babblers, so that I could not tell where one ended and the other began." Eggs all slightly incubated.

The seven eggs forming this clutch are so much alike that apparently they were laid by the same bird.—HENRY J. WHITE, "Belltrees," N.S.W. 11/6/1922.
