# Gamma Ray Intensity and Angular Correlation Measurements in ${ }^{160} \mathrm{Dy}$ 

S. S. Bhati, ${ }^{\text {A }}$ Nirmal Singh, ${ }^{\text {B }}$ P. D. Bajaj ${ }^{\text {A }}$ and P. N. Trehan ${ }^{\text {A }}$<br>${ }^{\text {A }}$ Department of Physics, Panjab University, Chandigarh-160014, India.<br>${ }^{\text {B }}$ Department of Applied Physics, Panjab Engineering College, Chandigarh, India.

#### Abstract

Gamma-ray intensity measurements in ${ }^{160} \mathrm{Dy}$ have been carried out using a $\mathrm{Ge}(\mathrm{Li})$ detector. In addition, $\gamma-\gamma$ angular correlation measurements have been made on 10 cascades in ${ }^{160} \mathrm{Dy}$ using a $\mathrm{Ge}(\mathrm{Li})-\mathrm{NaI}(\mathrm{Tl})$ fast coincidence arrangement. These cascades are $299 \rightarrow 966,299 \rightarrow 879,879 \rightarrow 87$, $197 \rightarrow 87,962 \rightarrow 87,215 \rightarrow 962,299 \rightarrow(879) \rightarrow 87,299 \rightarrow(682) \rightarrow 197,215 \rightarrow(962) \rightarrow 87$ and $215 \rightarrow(765) \rightarrow$ 197 keV . Of these, the $215 \rightarrow(962) \rightarrow 87$ and $215 \rightarrow(765) \rightarrow 197 \mathrm{keV}$ cascades have been measured for the first time. The multipolarities of the 197, 215, 299, 879 and 962 keV transitions were found to be $\mathrm{E} 2+(0 \cdot 2 \pm 0 \cdot 2) \% \mathrm{M} 3, \mathrm{E} 1+\left(2 \cdot 5_{-1.0}^{+1.5}\right) \% \mathrm{M} 2, \mathrm{E} 1+\left(2_{-2}^{+4}\right) \% \mathrm{M} 2, \mathrm{M} 1+(99 \pm 1) \% \mathrm{E} 2$ and $\mathrm{M} 1+$ $(98 \pm 1) \% \mathrm{E} 2$ respectively.

## Introduction

The radioisotope ${ }^{160} \mathrm{~Tb}$ decays to ${ }^{160} \mathrm{Dy}$ by $\beta$-emission with a half-life of 72.4 days. Dysprosium-160 is a doubly even nucleus in the deformed region and its level scheme has been studied by many workers (Nathan 1957; Ofer 1957; Arns et al. 1959; Ewan et al. 1961; Kundig 1961; Michaelis 1963; Gupta and Saha 1965) using scintillation, curved-crystal and magnetic spectrometers. Recently the decay scheme of ${ }^{160} \mathrm{~Tb}$ has been investigated using a $\mathrm{Ge}(\mathrm{Li})$ spectrometer (Ludington et al. 1968; Keller and Zganjar 1970; McAdams and Ottesson 1972; Roehmer 1973). While several new $\gamma$ rays proposed by Ludington et al. have been subsequently verified by Keller and Zganjar and by McAdams and Ottesson, there is some disagreement between the relative intensities of some of the $\gamma$ rays as measured by these workers.

Spin and parity assignments to most of the levels in ${ }^{160}$ Dy have been made using the angular correlation method (Nathan 1957; Ofer 1957; Arns et al. 1959; Kundig 1961; Michaelis 1963) and internal conversion measurements (Ewan et al. 1961). The angular correlation studies were carried out with scintillation detectors in all these investigations. Since then Jaklevic et al. (1967), Krane and Steffen (1971) and Zawislak et al. (1973) have made angular correlation measurements in the case of ${ }^{160} \mathrm{Dy}$ using $\mathrm{Ge}(\mathrm{Li})-\mathrm{NaI}(\mathrm{Tl}), \mathrm{Ge}(\mathrm{Li})-\mathrm{Ge}(\mathrm{Li})$ and $\mathrm{Ge}(\mathrm{Li})-\mathrm{NaI}(\mathrm{Tl})$ combinations respectively. The results of these workers, however, are not in good agreement with each other. In addition, the angular correlation of some of the cascades has not been measured so far by scintillation or by $\mathrm{Ge}(\mathrm{Li})$ detectors.

In view of the above-mentioned discrepancies, it was thought worth while to re-investigate the decay scheme of ${ }^{160} \mathrm{~Tb}$. In the present work, the level scheme of ${ }^{160} \mathrm{Dy}$ has been studied using a $\mathrm{Ge}(\mathrm{Li})$ spectrometer in the singles mode. In addition, angular correlations for the following 10 cascades in ${ }^{160} \mathrm{Dy}$, namely $299 \rightarrow 966$,
$299 \rightarrow 879,879 \rightarrow 87,197 \rightarrow 87,962 \rightarrow 87,215 \rightarrow 962,299 \rightarrow(879) \rightarrow 87,299 \rightarrow(682) \rightarrow 197$, $215 \rightarrow(962) \rightarrow 87$ and $215 \rightarrow(765) \rightarrow 197 \mathrm{keV}$, have been studied using $\mathrm{Ge}(\mathrm{Li})-\mathrm{NaI}(\mathrm{Tl})$ detectors in the fast coincidence mode. From these studies, it has been possible to measure the relative intensities of various $\gamma$ rays in ${ }^{160} \mathrm{Dy}$ and to assign multipolarities to the 197, 215, 299, 879 and $962 \mathrm{keV} \gamma$ rays. Fig. 1 shows the decay scheme of ${ }^{160} \mathrm{~Tb}$, and the level scheme of ${ }^{160} \mathrm{Dy}$ which is consistent with the present measurements.

Fig. 1. Decay scheme of ${ }^{160} \mathrm{~Tb}$, and the level scheme of ${ }^{160} \mathrm{Dy}$ which is consistent with the present measurements. ${ }^{160} \mathrm{~Tb}$ has $I^{\pi}=3^{-}$.

## Experimental Arrangement and Data Analysis

The ${ }^{160} \mathrm{~Tb}$ radioactive source in the form of terbium chloride in dilute hydrochloric acid was obtained from the Bhabha Atomic Research Centre. From this active solution, sources of different strengths were prepared in cylindrical Perspex holders with central cavities of 1.5 mm diameter and 4 mm depth. A $7.77 \mathrm{~cm}^{3} \mathrm{Ge}(\mathrm{Li})$ detector and an ND-1100 multichannel analyser were used to measure the relative intensities of various $\gamma$ rays. The calibration of the $\mathrm{Ge}(\mathrm{Li})$ spectrometer was performed by the method of Gehrke et al. (1971).

The directional correlation measurements were made employing a $\mathrm{Ge}(\mathrm{Li})-\mathrm{NaI}(\mathrm{Tl})$ fast coincidence arrangement with an effective resolving time $\tau=50 \mathrm{~ns}$. The $\gamma$ rays were detected by a $7.77 \mathrm{~cm}^{3} \mathrm{Ge}(\mathrm{Li})$ detector on one side and a $5 \times 5 \mathrm{~cm} \mathrm{NaI}(\mathrm{Tl})$ detector mounted on a Dumont 6292 photomultiplier on the other side. The $\mathrm{NaI}(\mathrm{Tl})$ detector was shielded with an anti-Compton graded lead cylinder and lead cone.

The source was located at a distance of 10 cm from the $\mathrm{NaI}(\mathrm{Tl})$ crystal and 6 cm from the $\mathrm{Ge}(\mathrm{Li})$ detector at the point of intersection of the axes of the two detectors. The $\mathrm{NaI}(\mathrm{Tl})$ detector could be moved to different angular positions whereas the $\mathrm{Ge}(\mathrm{Li})$ detector was kept fixed. The centring of the source was achieved to within $1 \%$ variation in the singles counting rate of the movable detector at various angular positions. Chance coincidences were recorded by introducing an appropriate delay in one channel of the fast coincidence setup.

The least squares fitting method of Rose (1953) was used to obtain the correlation functions. Solid angle corrections were made by using the correction factors calculated by Yates (1965) for $\mathrm{NaI}(\mathrm{Tl})$ crystals. The correction factors for the $\mathrm{Ge}(\mathrm{Li})$ detector were calculated using the technique of Camp and Vanlehn (1969).

The 87 and $299 \mathrm{keV} \gamma$ rays were selected by the gate set on the $\mathrm{NaI}(\mathrm{Tl})$ detector side and the $197,215,879,962$ and $966 \mathrm{keV} \gamma$ rays were selected by the gate set on the $\mathrm{Ge}(\mathrm{Li})$ detector side for the eight cascades that were studied which involved these $\gamma$ rays. For the $215 \rightarrow 962$ and $215 \rightarrow(765) \rightarrow 197 \mathrm{keV}$ cascades, the $215 \mathrm{keV} \gamma$ ray was selected by the gate set on the $\mathrm{NaI}(\mathrm{Tl})$ side. All cascades were corrected for interference through Compton events from higher energy $\gamma$ rays falling in the gates of the various lower energy $\gamma$ rays by use of the intensity data given in Table 1. In analysing the correlation functions to obtain mixing ratios, the methods of Arns and Wiedenbeck (1958) and Taylor et al. (1971) were used.

## Measurements and Results

Our measurements of the relative intensities of the $\gamma$ rays, as obtained with a $7.77 \mathrm{~cm}^{3} \mathrm{Ge}(\mathrm{Li})$ detector, are given in Table 1 along with those determined by Ludington et al. (1968). In general, there is good agreement between the two sets of results. Some of the very weak $\gamma$ rays were not observed in the present experiment. Measurements of the angular correlation coefficients for some cascades in ${ }^{160} \mathrm{Dy}$ are compared in Table 2 with the results of Krane and Steffen (1971). These are considered in more detail in the following subsections.

## (a) 299 $\rightarrow 996 \mathrm{keV}$ Cascade

The $299 \rightarrow 966 \mathrm{keV}$ cascade follows a spin sequence $2^{-}(D, Q) 2^{+}(Q) 0^{+}$. Assuming the $966 \mathrm{keV} \gamma$ ray to be pure E2 (Ewan et al. 1961), we found the multipole admixture in the $299 \mathrm{keV} \gamma$ ray by the method of Taylor et al. (1971). The two values of $\delta$ obtained are $-0.07 \leqslant \delta_{1} \leqslant 0.03$ and $-2.2 \leqslant \delta_{2} \leqslant-1.9$. The values $Q_{1}$ and $Q_{2}$ of $Q=\delta^{2} /\left(1+\delta^{2}\right)$ corresponding to $\delta_{1}$ and $\delta_{2}$ are given in Table 3 . The second value $Q_{2}$ is not in agreement with internal conversion measurements (Ewan et al.), and so the mixing ratio in the $299 \mathrm{keV} \gamma$ ray corresponds to $Q_{1}$ and is given by $\mathrm{E} 1+\left(0 \cdot 2_{-0 \cdot 1}^{+0 \cdot 3}\right) \% \mathrm{M} 2$.

## (b) $299 \rightarrow 879 \mathrm{keV}$ Cascade

The $299 \rightarrow 879 \mathrm{keV}$ cascade follows a spin sequence $2^{-}(D, Q) 2^{+}(D, Q) 2^{+}$. Assuming the $299 \mathrm{keV} \gamma$ ray to be $\mathrm{E} 1+(0 \cdot 5 \pm 0 \cdot 5) \% \mathrm{M} 2$, as determined by suitably averaging the results given in subsection (a) and subsection (g) below, the mixing ratio analysis of the $879 \mathrm{keV} \gamma$ ray yields the values of $Q$ given in Table 3. The $Q_{1}$ value is not in agreement with internal conversion measurements (Ewan et al. 1961), and so the 879 keV $\gamma$ ray is $\mathrm{M} 1+(99 \cdot 5 \pm 0 \cdot 5) \% \mathrm{E} 2$ in character.

(c) $879 \rightarrow 87 \mathrm{keV}$ Cascade

The $879 \rightarrow 87 \mathrm{keV}$ cascade involves the 87 keV state as the intermediate state whose half-life is 2.0 ns . Due to this long half-life, the observed angular correlation coefficients of the $879 \rightarrow 87 \mathrm{keV}$ cascade are attenuated and have to be corrected. The values of the attenuation coefficients $G_{22}$ and $G_{44}$ as determined by Gunther et al. (1965) for a similar source of $\mathrm{TbCl}_{3}$ in HCl solution were used for this correction, namely, $G_{22}=0.74 \pm 0.02$ and $G_{44}=0.594 \pm 0.025$. These values were also used to correct the correlation coefficients of the $197 \rightarrow 87,962 \rightarrow 87,299 \rightarrow(879) \rightarrow 87$ and $215 \rightarrow(962) \rightarrow 87 \mathrm{keV}$ cascades, which also involve the 87 keV state as the intermediate state. The $879 \rightarrow 87 \mathrm{keV}$ cascade follows a spin sequence $2^{+}(D, Q) 2^{+}(Q) 0^{+}$. Assuming the $87 \mathrm{keV} \gamma$ ray to be pure E 2 , the mixing ratio analysis for the $879 \mathrm{keV} \gamma$ ray yields $0 \cdot 36 \leqslant \delta_{1} \leqslant 0 \cdot 38$ and $-16 \cdot 0 \leqslant \delta_{2} \leqslant-13 \cdot 0$. The value $\delta_{1}$ is not supported by the experimental value for $A_{4}$. The corresponding $Q$ values are listed in Table 3. The mixing ratio of the $879 \mathrm{keV} \gamma$ ray is given by $\delta_{2}$, and its character is M1 $+(99 \cdot 0 \pm$ $1 \cdot 0) \% \mathrm{E} 2$. This value is in good agreement with that obtained by Jaklevic et al. (1967).

## (d) 197 $\rightarrow 87$ keV Cascade

The angular correlation coefficients for the $197 \rightarrow 87 \mathrm{keV}$ cascade given in Table 2 have been corrected for attenuation due to the half-life of the 87 keV level. This cascade follows a spin sequence $4^{+}(Q, 0) 2^{+}(Q) 0^{+}$. Assuming the $87 \mathrm{keV} \gamma$ ray to be pure E 2 , the mixing ratio analysis yields for the $197 \mathrm{keV} \gamma$ ray $0.004 \leqslant \delta_{1} \leqslant$ 0.06 and $1.30 \leqslant \delta_{2} \leqslant 1 \cdot 65$, which give the two values of $Q$ listed in Table 3. The $Q_{2}$ value does not agree with the internal conversion measurements (Ewan et al. 1961), so that the mixing ratio of the $197 \mathrm{keV} \gamma$ ray is $\mathrm{E} 2+(0 \cdot 2 \pm 0 \cdot 2) \% \mathrm{M} 3$.
(e) $962 \rightarrow 87 \mathrm{keV}$ Cascade

After correcting for attenuation due to the long half-life of the 87 keV state, the angular correlation coefficients of the $962 \rightarrow 87 \mathrm{keV}$ cascade are those given in Table 2. This cascade follows a spin sequence $3^{+}(D, Q) 2^{+}(Q) 0^{+}$. Assuming the $87 \mathrm{keV} \gamma$ ray to be pure E 2 , the mixing ratio analysis of the cascade yields for the $962 \mathrm{keV} \gamma$ ray the values of $Q_{1}$ and $Q_{2}$ given in Table 3. The $Q_{1}$ value is not in agreement with the internal conversion measurements (Ewan et al. 1961), and hence the multipole admixture in the $962 \mathrm{keV} \gamma$ ray is $\mathrm{M} 1+(98 \pm 1) \% \mathrm{E} 2$.

## (f) 215 $\rightarrow 962 \mathrm{keV}$ Cascade

The $215 \rightarrow 962 \mathrm{keV}$ cascade follows a spin sequence $2^{-}(D, Q) 3^{+}(D, Q) 2^{+}$. Assuming the $962 \mathrm{keV} \gamma$ ray to be $\mathrm{M} 1+(98 \pm 1) \% \mathrm{E} 2$ as determined in subsection (e), the mixing ratio analysis of the cascade yields the values of $Q_{1}$ and $Q_{2}$ for the 215 keV $\gamma$ ray given in Table 3. The $Q_{2}$ value is not supported by internal conversion measurements (Ewan et al. 1961), so that the $215 \mathrm{keV} \gamma$ ray is $\mathrm{E} 1+(1 \cdot 5 \pm 0 \cdot 5) \% \mathrm{M} 2$ in character.
(g) $299 \rightarrow(879) \rightarrow 87 \mathrm{keV}$ Cascade

The $299 \rightarrow(879) \rightarrow 87 \mathrm{keV}$ cascade is a $1 \rightarrow 3$ cascade, with the $879 \mathrm{keV} \gamma$ ray as the unobserved transition. The experimental angular correlation coefficients for such a cascade are given by

$$
A_{k k}(\exp )=A_{k}^{(1)} U_{k}(\text { unobs }) A_{k}^{(3)}
$$

where $k=2$ or 4 . The values of the coefficients $U_{k}$ for the $879 \mathrm{keV} \gamma$ ray were taken from the tables of Rose and Brink (1967). The spin sequence for the cascade is $2^{-} \rightarrow\left(2^{+} \rightarrow 2^{+}\right) \rightarrow 0^{+}$. Assuming the $87 \mathrm{keV} \gamma$ ray to be pure E2 and the 879 keV $\gamma$ ray to be $\mathrm{M} 1+(99 \cdot 0 \pm 1 \cdot 0) \% \mathrm{E} 2$ (subsection $c$ ), the mixing ratio analysis of the $299 \mathrm{keV} \gamma$ ray yields the $Q$ values given in Table 3. The $Q_{2}$ value is not compatible with the internal conversion measurements (Ewan et al. 1961), and therefore the $299 \mathrm{keV} \gamma$ ray is $\mathrm{E} 1+(1 \pm 1) \% \mathrm{M} 2$. This result is in good agreement with that derived in subsection (a).

Fig. 2. Experimental angular correlation coefficients $A_{k}^{(1)}(Q)$ for determining multipole mixing in the 215 keV transition from the analysis of (a) the $215 \rightarrow(962) \rightarrow 87$ and $(b) 215 \rightarrow(765) \rightarrow 197 \mathrm{keV}$ cascades.
(h) $215 \rightarrow(962) \rightarrow 87 \mathrm{keV}$ Cascade

The measurement of the angular correlation of the $215 \rightarrow(962) \rightarrow 87 \mathrm{keV}$ cascade was attempted for the first time. The angular correlation coefficients, after correcting for the attenuation due to the half-life of the 87 keV state are as given in Table 2. The cascade follows the spin sequence $2^{-} \rightarrow\left(3^{+} \rightarrow 2^{+}\right) \rightarrow 0^{+}$and is a $1 \rightarrow 3$ cascade, with the $962 \mathrm{keV} \gamma$ ray as the unobserved transition. The coefficients $U_{k}$ for the 962 keV transition were taken from the tables of Rose and Brink (1967) assuming the $962 \mathrm{keV} \gamma$ ray to be $\mathrm{M} 1+(98 \pm 1) \% \mathrm{E} 2$ in character (subsection e). Assuming the $87 \mathrm{keV} \gamma$ ray to be pure E 2 , the mixing ratio analysis of the cascade yields the
values of $Q$ for the $215 \mathrm{keV} \gamma$ ray given in Fig. 2a. The $Q_{2}$ value is not supported by the value of $A_{4}^{(1)}(\exp )$ as well as internal conversion measurements (Ewan et al. 1961). Therefore the $215 \mathrm{keV} \gamma$ ray is $\mathrm{E} 1+\left(2_{-2}^{+4}\right) \% \mathrm{M} 2$ in character. This result is in good agreement with the values derived in subsection $(f)$ and subsection ( $j$ ) below.

## (i) $299 \rightarrow(682) \rightarrow 197 \mathrm{keV}$ Cascade

The $299 \rightarrow(682) \rightarrow 197 \mathrm{keV}$ cascade is a $1 \rightarrow 3$ cascade, with the $682 \mathrm{keV} \gamma$ ray as the unobserved transition. The coefficients $U_{k}$ for the 682 keV transition in this cascade were determined from the table of Rose and Brink (1967) assuming the $682 \mathrm{keV} \gamma$ ray to be pure E 2 in character. The transition follows the spin sequence $2^{-} \rightarrow\left(2^{+} \rightarrow 4^{+}\right) \rightarrow 2^{+}$. Assuming the $197 \mathrm{keV} \gamma$ ray to be $\mathrm{E} 2+(0 \cdot 2 \pm 0 \cdot 2) \% \mathrm{M} 3$ in character, as found in subsection (d), the mixing ratio analysis yields the $Q$ values given in Table 3 for the quadrupole content of the 299 keV transition. The $Q_{2}$ value is not in agreement with internal conversion measurements (Ewan et al. 1961). Therefore the mixing ratio of the $299 \mathrm{keV} \gamma$ ray is $\mathrm{E} 1+(6 \pm 3) \% \mathrm{M} 2$.

## (j) 215 $\rightarrow$ (765) $\rightarrow 197 \mathrm{keV}$ Cascade

The measurement of the angular correlation of the $215 \rightarrow(765) \rightarrow 197 \mathrm{keV}$ cascade was attempted for the first time. Assuming a spin sequence of $2^{-} \rightarrow\left(3^{+} \rightarrow 4^{+}\right) \rightarrow 2^{+}$ for the cascade and an $\mathrm{E} 2+(0 \cdot 2 \pm 0 \cdot 2) \% \mathrm{M} 3$ admixture for the $197 \mathrm{keV} \gamma \mathrm{ray}$, and with the coefficients $U_{k}$ for the $765 \mathrm{keV} \gamma$ ray taken from Rose and Brink (1967) assuming this $\gamma$ ray to be pure E 2 , we obtained the $Q$ values for the 215 keV transition that are given in Table 3. The $Q_{2}$ value is not supported by internal conversion measurements (Ewan et al. 1961). Hence the 215 keV transition is E1 $+\left(2 \cdot 5_{-1 \cdot 0}^{+1 \cdot 5}\right) \%$ M2 in character (Fig. $2 b$ ). This is in good agreement with results obtained in subsections $(f)$ and (h).

Thus, in summary, our measurements for the relative intensities of $\gamma$ rays in ${ }^{160} \mathrm{Dy}$ are found to be in good agreement with those obtained by Ludington et al. (1968). We have established the multipolarities of the 197, $215,299,879$ and 962 keV $\gamma$ rays to be $\mathrm{E} 2+(0 \cdot 2 \pm 0 \cdot 2) \% \mathrm{M} 3, \mathrm{E} 1+\left(2 \cdot 5_{-1 \cdot 0}^{+1 \cdot 5}\right) \% \mathrm{M} 2, \mathrm{E} 1+\left(2_{-2}^{+4}\right) \% \mathrm{M} 2, \mathrm{M} 1+$ $(99 \pm 1) \% \mathrm{E} 2$ and $\mathrm{M} 1+(98 \pm 1) \% \mathrm{E} 2$ respectively.
