Abstract: In Australia, people from culturally and linguistically diverse backgrounds, largely born in low- and middle-income countries, accounted for 24% of HIV notifications in the period 2004–2008. NSW has one of the most culturally diverse communities in Australia and is also the most popular destination for both permanent and temporary migrants. Consequently people from culturally and linguistically diverse backgrounds have recently been recognised as a priority in the NSW HIV/AIDS Strategy. The National Health and Medical Research Council provides a cultural competency framework for re-orienting public health and health promotion programs to better meet the needs of these communities. It is being applied to re-orientate the HIV response in NSW. Examples of how this framework can be implemented are provided.

New South Wales (NSW) has one of the most culturally diverse communities in Australia, and people from culturally and linguistically diverse (CALD) backgrounds have recently been recognised as a priority in the NSW HIV/AIDS Strategy. This diversity presents challenges and opportunities for the human immunodeficiency (HIV) and acquired immunodeficiency syndrome (AIDS) sector in re-orienting health promotion, treatment and care services to better reach CALD communities in NSW. This paper will outline how cultural competency provides a framework for the re-orientation of the HIV response in NSW and provides specific examples of how this framework can be implemented.

Global population mobility and accelerating international migration to high-income countries has transformed the demography of most industrialised countries over the past 50 years. Population mobility and migration are historically some of the forces associated with the emergence and spread of infectious diseases by bringing populations with disparate prevalence rates into closer proximity with each other. This disparity is acute in the global incidence of HIV with more than 95% of annual HIV infections occurring in low- and middle-income countries. Migrants and mobile populations, especially those from low- and middle-income countries, may also have specific social vulnerabilities to HIV including social isolation, poverty, limited access to health services and information—all of which can be compounded by cultural and linguistic barriers in the destination country.

Migration to Australia
Australia’s annual migrant intake of about 150 000 permanent settlers is mostly made up of skilled and family migration with humanitarian entrants accounting for about 10 000 settlers. Since the mid 1980s all applicants for permanent migration to Australia undergo HIV testing as part of the health requirements. In addition, temporary migration, mostly made up of students and temporary skilled entrants, is on the rise, with NSW the most popular destination for both permanent settlers and temporary entrants.

HIV among people from CALD backgrounds
In Australia, people from CALD backgrounds, largely born in low- and middle-income countries, accounted for 24% of HIV notifications in the period 2004–2008. In 2008, people born in Asia and Sub-Saharan Africa made up 21% of all HIV notifications, with the highest age-standardised incidence rate among people born in Sub-Saharan Africa. This pattern of HIV among immigrants in Australia is broadly in line with trends seen in the European Union, the USA, and Canada.

The dominant modes of HIV transmission among people from CALD backgrounds in NSW tend to mirror epidemics in their regions of birth, with higher proportions of heterosexual transmission of HIV, and consequently higher proportions of women with HIV. Information describing ‘Country of birth’ and ‘language spoken at home’ has been collected with HIV notifications in NSW since the mid-1990s with reliable data available since 2000. An unpublished analysis of NSW HIV surveillance data from

Addressing challenges through a cultural competency framework

The HIV response in NSW has been well served by targeted primary and secondary interventions with the most affected communities; an approach that can also be employed with priority CALD communities. A systemic culturally competent approach along the lines proposed by the NHMRC would continue to work towards ensuring that we can capture, enumerate and measure diversity in surveillance to inform planning and prioritising programs for CALD communities in NSW.

Systemic approaches

The four dimensions of the framework – systemic, organisational, professional and individual – interrelate ‘so that cultural competence at an individual and professional level is underpinned by systemic and organisational commitment and capacity’.

Cultural competence within the health system is more than awareness of cultural differences and is best viewed as a developmental process for individual workers, the agency where they work and the health system in which they work.

Organisational approaches

An organisational approach requires agencies to reflect on and review current practices, policies and planning as a step towards delivering more culturally competent programs and services. The need for an organisational approach was highlighted in an HIV-sector needs analysis commissioned by the Multicultural HIV/AIDS and Hepatitis C Service in 2007. It found that HIV agencies perceived they lacked the knowledge, skills and self-efficacy to work with CALD communities.

A cultural competence training program subsequently developed by the Multicultural HIV/AIDS and Hepatitis C Service for the HIV sector focused on the development of an agency-level response to CALD populations. An evaluation of the training indicated that this model was effective in supporting organisations to identify and commit resources to future strategies to deliver a sustained response with priority CALD populations.
Professional and individual approaches
These approaches build the skills of individuals and professionals to work with cultural diversity, including understanding cultural dynamics and enhancing communication skills. Skills developed at this level build upon, and are supported by, systemic and organisational approaches. An example of this approach in NSW was recent work undertaken by the NSW CALD HIV Interagency which identified HIV and tuberculosis co-infection as a clinical priority affecting CALD populations. A revised HIV and tuberculosis policy directive was the systemic change that provided the impetus for workforce development initiatives with HIV, sexual health and tuberculosis services to enhance screening and improve the management of HIV and tuberculosis in CALD patients.

Conclusion
Guarding against the emerging epidemic of HIV in CALD communities will require proportionate and culturally-competent activity across the spectrum of the public health response to HIV in NSW in health promotion, treatment and care. This spectrum of activity should continue to refine HIV policy frameworks; build more detailed epidemiological profiles of homosexual and heterosexual transmission of HIV in CALD communities to better identify priority populations; and research the social contexts and understandings of HIV and AIDS in these populations. At the same time, efforts to enhance the cultural competence of HIV sector agencies and their staff will support the building of relationships, trust and partnerships with the most affected CALD communities to ensure that HIV interventions are culturally appropriate and less likely to stigmatise people with, or at risk of, HIV and AIDS.
