Accessory Materials

Calculations for the kinetic study of 4-nitrobenzyl 4-nitrobenzoate formation using (1)-(4)

Total volume = 150 mL (solvent) + diisopropylethylamine (1.74 mL) + triflic anhydride (0.34 mL) = 152.08 mL = 0.15208 L

$$[A]_o = [\text{initial 4-nitrobenzyl alcohol}] = \text{moles} / \text{vol (L)} = 0.002 / 0.15208 = 0.01315 \text{ M}$$

$$[A] = [\text{4-nitrobenzyl alcohol}] \text{ at time } t = (\% \text{ 4-nitrobenzyl alcohol at time } t / 100) * [\text{initial 4-nitrobenzyl alcohol}]$$

Pseudo first order conditions were achieved using 5 eq. 4-nitrobenzoic acid in 150 mL solvent at 0°C.

Rate constant (k) = - gradient (m).

$$T_{1/2} = \ln 2 / k$$
