1. General experimental

Unless otherwise stated, all reagents were purchased from commercial sources and used without further purification. A CEM S-class microwave reactor was used to carry out microwave enhanced reactions. ^1H and ^{13}C NMR were recorded on either a 400 MHz Varian MR or 500 MHz Varian AR spectrometer at 298 K. Chemical shifts (δ) are reported in parts per million (ppm) and referenced to residual solvent peaks (CDCl_3 : ^1H δ 7.26, ^{13}C δ 77.16 ppm; $d_6\text{-DMSO}$: ^1H δ 2.50 ppm, ^{13}C δ 39.50 ppm). Coupling constants (J) are reported in Hertz (Hz). Standard abbreviations indicating multiplicity were used as follows: m = multiplet, q = quartet, p = pentet, ddd = doublet of doublet of doublets, dt = doublet of triplet, dd = doublet of doublet, t = triplet, d = doublet, s = singlet. IR spectra were recorded on a Bruker ALPHA FT-IR spectrometer with an attached ALPHA-P measurement module. Microanalyses were performed at the Campbell Microanalytical Laboratory, University of Otago. High resolution electrospray mass spectra (HR-ESMS) were collected on a Bruker micrOTOF-Q spectrometer. UV-visible absorption spectra were acquired with a Perkin Elmer Lambda-950 spectrophotometer in DMF (10^{-5} M concentrations). Melting points were determined using a Leica VMHB melting bar. Bidentate 2-pyridyl-1,2,3-triazole ligands (**5a** and **5b**),¹ di-(2-pyridyl-1,2,3-triazole) ligands (**6a** and **6b**)² and rhenium complexes (**7a_{Cl}** and **7b_{Cl}**)³ were prepared by previously reported procedures.

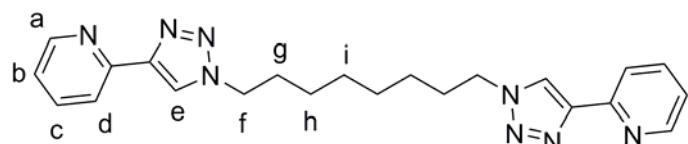

Safety Note: Whilst no problems were encountered during the course of this work, azide compounds are potentially explosive and appropriate precautions should be taken when working with them.

2. General procedure for the synthesis of the ligands

A dibromoalkane (1 eq.) and sodium azide (3 eq.) were dissolved in 4:1 DMF/H₂O (15 mL). The mixture was irradiated in a CEM microwave reactor at 125 °C (200 W, 200 PSI) for three hours. The mixture was stirred for 12 hours. The suspension was partitioned between

aqueous 0.1 M NH₄OH/EDTA (100 mL) and CH₂Cl₂ (100 mL) and the layers were separated. The organic phase was washed with water (100 mL) and brine (100 mL), dried over MgSO₄ and the solvent was removed under reduced pressure to obtain the ligand as an off-white solid.

4 General procedure for the synthesis of the cationic rhenium(I) complexes

One of the neutral mono- or di-rhenium bromide complexes and silver triflate (1.25 eq. or 2.5 eq.) were dissolved in dry CH₂Cl₂ (10 mL) and stirred at room temperature in the absence of light, for 12 hours. The reaction mixture was filtered through cotton wool and the solvent volume was removed under reduced pressure. The resultant golden yellow oil was re-dissolved in dry THF (8 mL), 4-dimethylaminopyridine (1 eq. or 2 eq.) was then added and the mixture was irradiated in a CEM microwave reactor at 100 °C (200 W, 200 PSI) for 1 hour. Removal of the solvent under reduced pressure and subsequent purification by silica gel column chromatography (10% MeOH in CH₂Cl₂), followed by recrystallization afforded the complexes as pale yellow solids.

Purification via column chromatography, followed by recrystallization from acetonitrile and diisopropyl ether led to the isolation of the product as a pale yellow solid.
