

THE CALIBRATION OF LINEAR SCALES BY THE METHOD OF HANSEN-PÉRARD

By E. G. THWAITE* and R. T. LESLIE†

[Manuscript received July 12, 1962]

Summary

The exact least-squares solutions for X_j^0 , X_i^0 and $\lambda_{(j-i)}$ of the set of equations $X_j^0 - X_i^0 - \lambda_{(j-i)} = b_{ji}$ ($i = 0, 1, \dots, n-1$; $j = 1, \dots, n$; $0 < (j-i) < n$), and for X_j^i , X_k^i and $\lambda_{(j-i)}$ of the set of equations

$$X_j^i - X_k^i - \lambda_{(j-i)} = b_{ji} \quad (j, i = 0, 1, \dots, m; |i-j| < m),$$

are obtained by matrix inversion. These sets of equations correspond to the "simple calibration" and the "cross calibration", of linear scales by the method of Hansen-Pérand. Tables are given of the inverses of the coefficient matrices of the normal equations for most practical cases and expressions are derived for the variance to be associated with any interval between calibrated scale graduations.

I. INTRODUCTION

The classical methods of scale calibration originally formulated by Hansen (1873) and developed by Pérand (1917) and referred to here, after Pérand, as the methods of "simple calibration" and "cross calibration", have an extensive literature (Judson 1927; Platanov 1941). The rigorous least-squares solution in the linear case is complicated, however, and the simplified method of Thiesen (1879), known as "graphical squares" or the "method of means" (Johnson 1923) has generally been used.

Unfortunately, unless special measures are taken to ensure that the reduced equations are statistically independent, as has been pointed out by Cook (1954), the Thiesen estimates do not in general correspond to the most probable values. To ensure independence between the entries in the squares in the Thiesen solution it is necessary to repeat sufficient of the observations for the entries in the square to be obtained from distinct observations. This is in fact what Gilet and Watson (1953) have done in their treatment of the subject, and it is contended, in disagreement with Cook, that the Gilet and Watson treatment is exact for the observational procedure adopted. When there is independence between the observations the reduced equations are independent, the Thiesen estimates are the most probable values, and the derivation of the variances given by Gilet and Watson follow in the case of both simple and cross calibration. When circular scales are treated in the manner of Gilet and Watson, symmetry is lost and a distinction is made between the graduations in the scheme of observation. It is then no longer true

* Division of Applied Physics, National Standards Laboratory, C.S.I.R.O., University Grounds, Chippendale, N.S.W.

† Division of Mathematical Statistics, National Standards Laboratory, C.S.I.R.O., University Grounds, Chippendale, N.S.W.

that the variance associated with an angle is independent of its position relative to some zero graduation, i.e. the zero of the scale is not arbitrary as it is when the scheme described by Cook is followed. The Thiesen procedure is, of course, always valid when distinct entities are being compared.

There is an advantage in using the exact least-squares solution in the linear case as set out by Pérard (1917), if the complexity of the arithmetic can be avoided, in that the number of observations necessary is of the order of half that required for the exact Thiesen solution. A large part of the computation can be avoided if the inverse of the coefficients matrix of the normal equations is available.

Experimentally the Hansen method is inferior in one respect to the rigorous Thiesen treatment. In the Thiesen treatment it is possible to arrange that the reduced equations are derived from the differences between successive pairs of microscope readings. These microscope readings are taken at very short time intervals and the danger of systematic errors due to relative microscope displacement is reduced. In the Hansen procedure the stability of the microscope separation must be reliable for a much longer period. The comparators used in subdivisional work of this nature, however, have been designed with this in view and extraordinary stability has been achieved by the methods of beam construction and support. Further, the observational procedure is usually such that all the observations of a given set can be reduced to refer to some specific time during the set, and in this way compensation is made for any linear changes which occur while the observations are being made.

While it is possible to estimate the microscope separations from the least-squares solution it is not possible to estimate the variance attributable to instability separately from the observational variance. The latter variance, however, has a component due to instability, and any marked change from its usual magnitude should be examined closely.

With the advent of the automatic digital computing machine, the inversion of the coefficients matrix of the normal equations is a relatively simple matter and once the inverse has been obtained it can be used whenever required. Tables of the inverses for a number of calibrations of various sizes for both simple and cross calibrations are given in the Appendices. The rigorous least-squares solutions, together with the corresponding variances and covariances, can then be obtained using these tables and a desk calculator.

In the following sections a method of obtaining the least-squares solutions of the equations resulting from the simple and cross calibration of a scale by the Hansen-Pérard method is given and the variance of the estimate of the interval between any pair of scale graduations is derived.

II. NOTATION

As the use of symbols in the literature is not uniform, a nomenclature is introduced which, without being unduly complex, allows the various cases to be shown clearly. In later sections use is made of matrix notation as being the best means of expressing results which would otherwise be extremely cumbersome.

The matrix treatment of least squares in the general linear case will be found in a recent work by Plackett (1960).

General formulae have been given to cover most particular cases. While the analysis is given in terms of linear scales it will be found to be appropriate in a number of other fields of measurement.

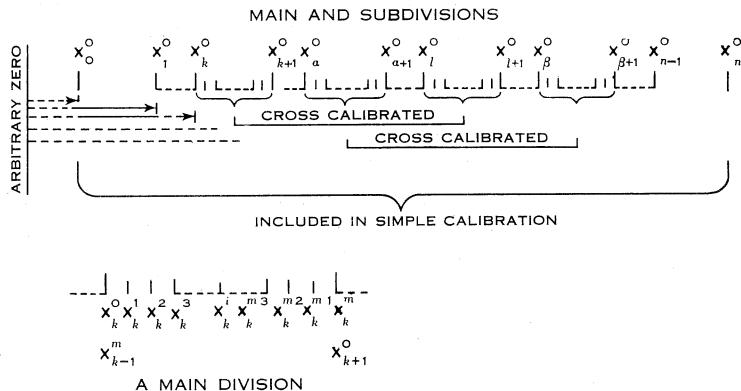

Fig. 1.—Illustration of notation.

The hierarchy of calibrations treated here is illustrated in Figure 1. Intervals are given in terms of differences from nominal length and positions are defined with respect to an arbitrary zero to the left of X_0^0 . It is assumed that there are n main divisions with leading ends at $X_0^0, X_1^0, X_2^0, \dots, X_k^0, \dots, X_{n-1}^0$ respectively. The comparisons of the scale against a reference standard to determine the deviations of X_0^0 and X_n^0 from their nominal positions is the sole reference to an outside standard; this determination is assumed to introduce uncertainties measured by their variances, $\sigma_{X_0^0}^2, \sigma_{X_n^0}^2$, and their covariance $\sigma_{X_0^0 X_n^0}$. Most frequently X_0^0 equals zero identically, i.e. the zero is taken at X_0^0 ; then $\sigma_{X_0^0}^2$ and $\sigma_{X_0^0 X_n^0}$ are zero. The notation X_k^0 will be used to mean either the graduation or its deviation from nominal position; no confusion should result from this double use of symbols.

A simple calibration now serves to determine the deviations of the main graduations $X_1^0, X_2^0, \dots, X_{n-1}^0$ from their nominal positions.

Two cross calibrations are shown: the m subdivisions contained in $X_k^0 X_{k+1}^0$ have been involved in a cross calibration with those of $X_l^0 X_{l+1}^0$; the m subdivisions of $X_a^0 X_{a+1}^0$, have been involved in a cross calibration with those of $X_\beta^0 X_{\beta+1}^0$. By extension of the nomenclature, X_k^i is taken to mean the i th graduation of the main division $X_k^0 X_{k+1}^0$. This leads to a small amount of redundancy in that the main graduations have two equivalent symbols; thus X_k^m , meaning the trailing end of the m th subdivision of $X_k^0 X_{k+1}^0$, is also the leading end of a main division, in which context it is written equivalently as X_{k+1}^0 .

It will be seen later that in allocating variances to intervals between graduations of the scale, cases fall into distinct groups which are now defined according to the graduations being used.

1. End-points falling upon main graduations:
 - (a) End-points falling on main graduations other than X_0^0 and X_n^0 .
 - (b) End-points falling on either X_0^0 or X_n^0 and on one of the other main graduations.
2. End-points falling within main divisions involved in the same cross calibration:
 - (a) Both end-points within the left-hand division of the cross calibration, typified by $X_k^i X_k^j$.
 - (b) Both end-points within the right-hand division of the cross calibration, typified by $X_l^i X_l^j$.
 - (c) One end-point within the left-hand division, and the other within the right-hand division, typified by $X_k^i X_l^j$.
3. End-points falling within main divisions involved in different cross calibrations:
 - (a) Typical end-points: $X_k^i X_a^j$.
 - (b) Typical end-points: $X_l^i X_\beta^j$.
 - (c) Typical end-points: $X_l^i X_a^j$.
 - (d) Typical end-points: $X_k^i X_\beta^j$.
4. One end-point falling upon a main graduation, the other end-point within a main division, typified by

(a) $X_t^0 X_k^i$
(b) $X_t^0 X_l^i$
}
including the cases $t = k, l, 0$, or n .

In using a scale, a knowledge is required not only of the positions of the graduations with respect to some zero but also of the errors in the intervals from any one calibrated graduation to any other calibrated graduation. For example, the error in the interval X_p^0 to X_q^0 is obtained by subtracting the estimate of X_p^0 from that of X_q^0 , and the variance to be associated with the length of this interval, as a measure of the uncertainty of the result, is given by

$$\text{Var}(X_p^0 - X_q^0) = \text{Var}(X_p^0) + \text{Var}(X_q^0) - 2 \text{Cov}(X_p^0, X_q^0).$$

One of the advantages of the matrix method of solution of the normal equations is that it yields not only the variances of each of the estimated lengths but also the covariance required for determining the uncertainty of any interval not commencing at the zero. In this respect the following notation is introduced: $\text{Cov}(X_k^0, X_l^0) = \sigma_{X_k^0 X_l^0}$ is the covariance of the quantities X_k^0 and X_l^0 ; it measures the correlation between these quantities arising jointly from the simple calibration and from the errors made in determining X_0^0 and X_n^0 .

In particular, when $k = l$, $\text{Cov}(X_k^0, X_k^0)$ is $\text{Var}(X_k^0)$, the variance of X_k^0 , which is also written $\sigma_{X_k^0}^2$.

$[\text{Cov}(X_k^0, X_l^0)]$ is the set of variances and covariances written as an $(n+1) \times (n+1)$ array as k, l separately run through the values 0, 1, ..., n , and is referred to as the variance-covariance matrix of the X^0 's.

When superscripts other than 0 occur, as in X_k^i , X_k^j (referring to the i th and the j th graduations of the m subdivisions of a main division) the array will be found by allowing i, j to take separately the values 1, 2, ..., m in succession, as in

$$[\text{Cov} (X_k^i, X_k^j)].$$

Simple and cross calibrations are considered in the next two sections. It will be shown later how estimates of the variance-covariance matrices are obtained.

III. SIMPLE CALIBRATION

The set of observational equations is

$$\begin{aligned} X_j^0 - X_i^0 - \lambda_{(j-i)} &= b_{ji}, \quad i = 0, 1, \dots, n-1; \\ j &= 1, \dots, n; \\ 0 < (j-i) &< n, \end{aligned}$$

where $\lambda_{(j-i)}$ is the deviation of the microscope separation from the nominal separation and b_{ji} is the observed quantity. There are then $\frac{1}{2}(n-1)(n+2)$ equations involving $2(n-1)$ unknowns of which $(n-1)$ are λ 's; of the $(n+1)$ X 's, X_0^0 and X_n^0 are known, leaving $(n-1)$ unknown X 's.

The observational equations are written in vector form as

$$\mathbf{AX} = \mathbf{a},$$

where

$$\mathbf{A} = \left[\begin{array}{cccccc|ccccccccc} -1 & 0 & 0 & 0 & \dots & 0 & 1 & 0 & 0 & 0 & 0 & \dots & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & \dots & 0 & -1 & 1 & 0 & 0 & 0 & \dots & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & 0 & 0 & \dots & 0 & 0 & -1 & 1 & 0 & 0 & \dots & 0 & 0 & 0 & 0 & 0 \\ \dots & \dots \\ -1 & 0 & 0 & 0 & \dots & 0 & 0 & 0 & 0 & 0 & 0 & \dots & 0 & 0 & -1 & 1 \\ -1 & 0 & 0 & 0 & \dots & 0 & 0 & 0 & 0 & 0 & 0 & \dots & 0 & 0 & 0 & -1 \\ 0 & -1 & 0 & 0 & \dots & 0 & 0 & 1 & 0 & 0 & 0 & \dots & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & \dots & 0 & -1 & 0 & 1 & 0 & 0 & \dots & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & \dots & 0 & 0 & -1 & 0 & 1 & 0 & \dots & 0 & 0 & 0 & 0 \\ \dots & \dots \\ 0 & -1 & 0 & 0 & \dots & 0 & 0 & 0 & 0 & 0 & 0 & \dots & 0 & -1 & 0 & 1 \\ 0 & -1 & 0 & 0 & \dots & 0 & 0 & 0 & 0 & 0 & 0 & \dots & 0 & 0 & -1 & 0 \\ 0 & 0 & -1 & 0 & \dots & 0 & 0 & 0 & 1 & 0 & 0 & \dots & 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 & \dots & 0 & -1 & 0 & 0 & 1 & 0 & \dots & 0 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 & \dots & 0 & 0 & -1 & 0 & 0 & 1 & \dots & 0 & 0 & 0 & 0 \\ \dots & \dots \\ 0 & 0 & -1 & 0 & \dots & 0 & 0 & 0 & 0 & 0 & 0 & \dots & -1 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 & \dots & 0 & 0 & 0 & 0 & 0 & 0 & \dots & 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & -1 & \dots & 0 & 0 & 0 & 0 & 1 & 0 & \dots & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & \dots & 0 & -1 & 0 & 0 & 0 & 1 & \dots & 0 & 0 & 0 & 0 \\ \dots & \dots \\ 0 & 0 & 0 & 0 & \dots & -1 & 0 & 0 & 0 & 0 & 0 & \dots & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & \dots & -1 & -1 & 0 & 0 & 0 & 0 & \dots & 0 & 0 & 0 & 0 \end{array} \right]$$

$$\mathbf{X} = \begin{bmatrix} \lambda_1 \\ \lambda_2 \\ \vdots \\ \lambda_{n-1} \\ X_1^0 \\ X_1 \\ \vdots \\ X_{n-1}^0 \end{bmatrix}, \quad \text{and} \quad \mathbf{a} = \begin{bmatrix} b_{10} + X_0^0 \\ b_{21} \\ \vdots \\ b_{n(n-1)} - X_n^0 \\ b_{20} + X_0^0 \\ b_{31} \\ \vdots \\ b_{n(n-2)} - X_n^0 \\ \vdots \\ b_{(n-1)0} + X_0^0 \\ b_{n1} - X_n^0 \end{bmatrix}.$$

The general element of the vector \mathbf{a} is

$$b_{ji} + \delta_{i0} X_0^0 - \delta_{jn} X_n^0,$$

where

$$\begin{aligned} \delta_{ab} &= 0, \quad a \neq b, \\ &= 1, \quad a = b. \end{aligned}$$

It will be seen that the elements of \mathbf{a} are the observations b_{ji} corrected for the value of X_0^0 and X_n^0 whenever they occur in the observational equations, i.e. these two values are brought to the right-hand side of the equations.

Least-squares procedure results in the normal equations

$$\mathbf{A}^T \hat{\mathbf{A}} - \mathbf{A}^T \mathbf{a} = 0;$$

the solution is written $\hat{\mathbf{X}} = (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{A}^T \mathbf{a}$.

The residual sum of squares is $\mathbf{a}^T \mathbf{a} - \hat{\mathbf{X}}^T \mathbf{A}^T \mathbf{a}$, from which, on division by $\frac{1}{2}(n-1)(n-2)$, one obtains the estimate s^2 of the observational variance. The estimated variance-covariance matrix for the main divisions, not including X_0^0 or X_n^0 and ignoring any contribution from the uncertainties of these two quantities, is

$$s^2(\mathbf{A}^T \mathbf{A})^{-1}.$$

The quantities are all readily computed. The inverse matrix $(\mathbf{A}^T \mathbf{A})^{-1}$ has been tabulated for $n = 4, 5, 6, 8, 10, 12$ in Appendix I. The vector $\mathbf{A}^T \mathbf{a}$ is obtained directly as the product of the transpose of the observational matrix \mathbf{A} and the column vector of the observed deviations b_{ji} corrected for X_0^0 and X_n^0 . The vector $\hat{\mathbf{X}}$ is then the product of $(\mathbf{A}^T \mathbf{A})^{-1}$ with the column vector $\mathbf{A}^T \mathbf{a}$. The scalar product $\mathbf{a}^T \mathbf{a}$ is the sum of squares of the $\frac{1}{2}(n-1)(n+2)$ observed quantities corrected for X_0^0 , X_n^0 , as described; if $\hat{\mathbf{X}}^T \mathbf{A}^T \mathbf{a}$ is subtracted from it the residual sum of squares is the remainder.

Example: For illustration, the procedure will be applied to the data of Table 1 from a simple calibration involving four main divisions. The quantities given under the heading "Comparison" are the subscripts of main divisions wherein, for example, 0/1 indicates the interval X_0^0 to X_1^0 ; the values listed under b are the observed quantities with signs in accordance with the observational equations already given.

TABLE 1
SIMPLE CALIBRATION: $n = 4$
Unit: 10^{-6} in.

| Comparison | b | Comparison | b | Comparison | b |
|------------|-----|------------|-----|------------|-----|
| 0/1 | -37 | 0/2 | 0 | 0/3 | +24 |
| 1/2 | -14 | 1/3 | 0 | 1/4 | -16 |
| 2/3 | -33 | 3/4 | -75 | | |
| 3/4 | -91 | | | | |

$$X_0^0 = 0; X_n^0 = 221; s_{X_0^0}^2 = 0, s_{X_n^0}^2 = 117 \times 10^{-12} \text{ in}^2, s_{X_0^0 X_n^0} = 0$$

For simplicity \mathbf{A} , not \mathbf{A}^T , is written followed by the column vector \mathbf{a} , whence $\mathbf{A}^T \mathbf{a}$ is computed by taking cross products of the columns of \mathbf{A} in succession with the vector \mathbf{a} . Thus \mathbf{A} , \mathbf{a} are written

$$\left[\begin{array}{cccccc} -1 & 0 & 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & -1 & 1 & 0 \\ -1 & 0 & 0 & 0 & -1 & 1 \\ -1 & 0 & 0 & 0 & 0 & -1 \\ 0 & -1 & 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & -1 & 0 & 1 \\ 0 & -1 & 0 & 0 & -1 & 0 \\ 0 & 0 & -1 & 0 & 0 & 1 \\ 0 & 0 & -1 & -1 & 0 & 0 \end{array} \right], \quad \left[\begin{array}{c} -37 \\ -14 \\ -33 \\ -91 \\ -221 \\ 0 \\ 0 \\ -75 \\ 24 \\ -16 \\ -221 \end{array} \right],$$

so that

$$\mathbf{A}^T \mathbf{a} = \left[\begin{array}{c} 37 + 14 + 33 + 312 \\ 0 + 0 + 296 \\ -24 + 237 \\ -37 + 14 + 237 \\ -14 + 33 + 296 \\ -33 + 312 + 24 \end{array} \right] = \left[\begin{array}{c} 396 \\ 296 \\ 213 \\ 214 \\ 315 \\ 303 \end{array} \right],$$

$$\mathbf{a}^T \mathbf{a} = 37^2 + 14^2 + 33^2 + 312^2 + \dots + 237^2 = 244359.$$

The inverse matrix $(\mathbf{A}^T \mathbf{A})^{-1}$ is symmetrical, so $\hat{\mathbf{X}} = (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{A}^T \mathbf{a}$ may be interpreted as row \times column or column \times column multiplication, and for ease of computation the latter is chosen, i.e. multiply $\mathbf{A}^T \mathbf{a}$ in succession by the columns of $(\mathbf{A}^T \mathbf{A})^{-1}$, taken from Table 1·1, Appendix I. Thus

$$\hat{\mathbf{X}} = (1/20) \begin{bmatrix} (\mathbf{A}^T \mathbf{A})^{-1} \\ 5 & 0 & 0 & 0 & 0 & 0 \\ 0 & 8 & 2 & -2 & 0 & 2 \\ 0 & 2 & 13 & -3 & 0 & 3 \\ 0 & -2 & -3 & 7 & 2 & 1 \\ 0 & 0 & 0 & 2 & 6 & 2 \\ 0 & 2 & 3 & 1 & 2 & 7 \end{bmatrix} \begin{bmatrix} \mathbf{A}^T \mathbf{a} \\ 396 \\ 296 \\ 213 \\ 214 \\ 315 \\ 303 \end{bmatrix} = (1/20) \begin{bmatrix} 1980 \\ 2972 \\ 3628 \\ 1200 \\ 2924 \\ 4196 \end{bmatrix} = \begin{bmatrix} 99.0 \\ 148.6 \\ 181.4 \\ 60.0 \\ 146.2 \\ 209.8 \end{bmatrix}$$

The vector $\hat{\mathbf{X}}^T \mathbf{A}^T \mathbf{a}$ is conveniently computed by writing $\hat{\mathbf{X}}$ and $\mathbf{A}^T \mathbf{a}$ side by side and summing the products of the pairs of numbers on the one line:

$$(1/20) \begin{bmatrix} 1980 \\ 2972 \\ 3628 \\ 1200 \\ 2924 \\ 4196 \end{bmatrix} \begin{bmatrix} 396 \\ 296 \\ 213 \\ 214 \\ 315 \\ 303 \end{bmatrix} = (1/20) \{(1980 \times 396) + (2972 \times 296) + \dots + (4196 \times 303)\} \\ = 244290.$$

Hence $s^2 = (244359 - 244290)/3 = 23$.

The only portion of the variance-covariance matrix of interest is the 3×3 submatrix in the lower right-hand corner of $s^2(\mathbf{A}^T \mathbf{A})^{-1}$, which is

$$(23/20) \begin{bmatrix} 7 & 2 & 1 \\ 2 & 6 & 2 \\ 1 & 2 & 7 \end{bmatrix} = \begin{bmatrix} 8 & 2 & 1 \\ 2 & 7 & 2 \\ 1 & 2 & 8 \end{bmatrix}.$$

We now have to take account of the variances and covariances of the determinations of X_0^0 and X_n^0 listed at the bottom of Table 1, and of the covariances between these two quantities and X_1^0 , X_2^0 , X_3^0 ; this corresponds to 1(b) of the groupings mentioned in Section II.

The solution for X_k^0 may be written* alternatively as

$$\hat{X}_k^0 = \hat{x}_k^0 + (k/n)(X_n^0 - X_0^0),$$

where $\hat{\mathbf{x}}^0 = (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{A}^T \mathbf{b}$.

* To avoid complexity in the notation, the circumflex, $\hat{\cdot}$, indicating "estimate", has been omitted where confusion is unlikely to arise.

Hence for k or l having the values 1, 2, ..., $n-1$,

$$\begin{aligned} [\text{Cov } (X_k^0, X_l^0)] &= [\text{Cov } (x_k^0, x_l^0)] + [(kl/n^2)\sigma_{(X_n^0 - X_0^0)}^2] \\ &= \sigma^2(\mathbf{A}^T \mathbf{A})^{-1} + [(kl/n^2)\sigma_{(X_n^0 - X_0^0)}^2] \\ &= \sigma^2(\mathbf{A}^T \mathbf{A})^{-1} + [(kl/n^2)\sigma_{X_n^0}^2], \end{aligned}$$

when X_0^0 is identically zero.

By similar reasoning, for one of the components equal to X_0^0 or X_n^0

$$\text{Cov } (X_0^0, X_k^0) = (k/n) \text{Cov } (X_0^0, X_n^0).$$

When X_0^0 is identically zero,

$$\text{Cov } (X_0^0, X_k^0) = 0,$$

and

$$\text{Cov } (X_k^0, X_n^0) = (k/n)\sigma_{X_n^0}^2.$$

In the example, then, the elements of the 3×3 variance-covariance matrix are augmented by allocation of $s_{X_n^0}^2 = 117$ in the proportion $(kl/16)$ and the addition of a row and column corresponding to $(k/n)s_{X_n^0}^2$, giving

$$117 \begin{bmatrix} 1/16 & 2/16 & 3/16 & 1/4 \\ 2/16 & 4/16 & 6/16 & 2/4 \\ 3/16 & 6/16 & 9/16 & 3/4 \\ 1/4 & 2/4 & 3/4 & 1 \end{bmatrix},$$

leading finally to

$$[\text{Cov } (X_k^0, X_l^0)] = \begin{bmatrix} 15 & 17 & 23 & 29 \\ 17 & 36 & 46 & 58 \\ 23 & 46 & 74 & 88 \\ 29 & 58 & 88 & 117 \end{bmatrix},$$

where the unit is 10^{-12} in 2 .

The variance of any specified interval may now be obtained immediately using the propagation of variance formula given in Section II.

IV. CROSS CALIBRATION

Apart from mechanical limitations, a cross calibration may be made between the subdivisions of any pair of main divisions of a scale. Several such cross calibrations could be made and the analysis would follow the same pattern in each case.

In a single cross calibration involving m subdivisions, (m^2+2m-1) observations are taken and a total of $(4m-3)$ constants have to be fitted; $(2m-1)$ of these refer to the microscope separations and $2(m-1)$ to the subdivisional graduations.

From a cross calibration between the intervals $X_k^0 X_k^m$ and $X_l^0 X_l^m$ the following set of (m^2+2m-1) observational equations with $(4m-3)$ unknowns is obtained:

$$\begin{aligned} X_l^i - X_k^i - \lambda_{(j-i)} &= b_{ji}, \quad j = 0, 1, \dots, m; \\ i &= 0, 1, \dots, m; \quad |i-j| < m. \end{aligned}$$

Following the notation used before, we write

$$\mathbf{AX} = \mathbf{a},$$

where \mathbf{A} is the coefficients matrix of the observational equations,

$$\mathbf{X} = \begin{bmatrix} \lambda_{-(m-1)} \\ \lambda_{-(m-2)} \\ \vdots \\ \vdots \\ \lambda_0 \\ \vdots \\ \vdots \\ \lambda_{(m-1)} \\ X_k^1 \\ \vdots \\ \vdots \\ X_k^{m-1} \\ X_l^1 \\ \vdots \\ \vdots \\ X_l^{m-1} \end{bmatrix} \text{ and } \mathbf{a} = \begin{bmatrix} b_{0(m-1)} - X_l^0 \\ b_{1m} + X_k^m \\ b_{0(m-2)} - X_l^0 \\ b_{1(m-1)} \\ b_{2m} + X_k^m \\ b_{0(m-3)} - X_l^0 \\ \vdots \\ \vdots \\ b_{00} + X_k^0 - X_l^0 \\ \vdots \\ \vdots \\ b_{mm} + X_k^m - X_l^m \\ b_{10} + X_k^0 \\ \vdots \\ \vdots \\ b_{m1} - X_l^m \end{bmatrix},$$

where the vector \mathbf{b} has been modified to \mathbf{a} by transferring X_k^0 , X_k^m , X_l^0 , X_l^m , whenever they occur, to the right-hand side of the observational equations.

The general element of the vector \mathbf{a} is

$$b_{ji} - \delta_{0j} X_l^0 + \delta_{mi} X_k^m + \delta_{0i} X_k^0 - \delta_{mj} X_l^m,$$

where

$$\begin{aligned} \delta_{ab} &= 0, & a \neq b, \\ &= 1, & a = b. \end{aligned}$$

The solution for \mathbf{X} is then

$$\hat{\mathbf{X}} = (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{A}^T \mathbf{a}.$$

Example: This example is a continuation of the example treated in the case of simple calibration. The main divisions involved are X_0^0 , X_1^0 and X_2^0 , X_3^0 of that example. In Table 2 the observed quantities b_{ji} are given.

The observational matrix \mathbf{A} and the vector \mathbf{a} are tabulated in Table 3.

The calculation proceeds as for the simple case. The vector $\mathbf{A}^T \mathbf{a}$ is obtained by forming the product of \mathbf{A} , column by column, with the column vector \mathbf{a} ; for convenience, this vector is written transposed at the foot of \mathbf{A} in Table 3. It is worth while to run a check on $\mathbf{A}^T \mathbf{a}$ by adding all its elements and checking this

sum against the product of \mathbf{a} and the vector which is the row sum of \mathbf{A} . The $(4m-3) \times (4m-3)$ inverse matrix $(\mathbf{A}^T \mathbf{A})^{-1}$ is given in Table 2.2, Appendix II; its product with $\mathbf{A}^T \mathbf{a}$ is now obtained and yields the solution $\hat{\mathbf{X}} = (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{A}^T \mathbf{a}$ of the normal equations. Unfortunately, all the $(4m-3)$ elements of $\hat{\mathbf{X}}$ are required in computing the residual error, although the first $(2m-1)$, which refer to the arbitrary microscope separations, are not otherwise needed. The quantities of direct interest are the last $2(m-1)$ elements. The first $(m-1)$ of these correspond to the deviations from nominal length of the subdivisions of $X_k^0 X_{k+1}^0$ and the second $(m-1)$ to the deviations from nominal length of the subdivisions of $X_l^0 X_{l+1}^0$.

TABLE 2
CROSS CALIBRATION: $m = 5$
 $b_{ji}; i = 0, \dots, 5; j = 0, \dots, 5$
Unit: 10^{-6} in.

| i | 0 | 1 | 2 | 3 | 4 | 5 |
|-----|-----|-----|-----|-----|-----|-----|
| j | | | | | | |
| 0 | -12 | +55 | 0 | 0 | 0 | — |
| 1 | 0 | -59 | -31 | -8 | -39 | -31 |
| 2 | -16 | 39 | -79 | 8 | 16 | -16 |
| 3 | -24 | 8 | -39 | -31 | 24 | 24 |
| 4 | 0 | 31 | -16 | 43 | -12 | 47 |
| 5 | — | 8 | -39 | 12 | 43 | -20 |

$X_0^0 = 0; X_1^0 = 60; X_2^0 = 146; X_3^0 = 210$

The sum of squares, $\mathbf{a}^T \mathbf{a}$, of the elements of \mathbf{a} , is now computed and then the product of the vectors $\hat{\mathbf{X}}, \mathbf{A}^T \mathbf{a}$; as before, $\mathbf{a}^T \mathbf{a} - \hat{\mathbf{X}}^T \mathbf{A}^T \mathbf{a}$ is the residual sum of squares, based on $(m^2 - 2m + 2)$ degrees of freedom, the divisor for the calculation of the residual variance.

We have then in the present example

$$\hat{\mathbf{X}} = (\mathbf{A}^T \mathbf{A})^{-1} (117, 141, 54, \dots, 153)^T,$$

where $(\mathbf{A}^T \mathbf{A})^{-1}$ is given in Table 2.2, Appendix II; we find

$$\begin{aligned} \hat{\mathbf{X}}^T = [& 92 \cdot 1, 105 \cdot 4, 81 \cdot 7, 92 \cdot 8, 165 \cdot 0, 121 \cdot 0, \\ & 158 \cdot 9, 182 \cdot 5, 205 \cdot 0, -3 \cdot 1, 65 \cdot 1, 40 \cdot 0, \\ & 49 \cdot 8, 117 \cdot 0, 148 \cdot 1, 162 \cdot 6, 205 \cdot 0], \end{aligned}$$

and

$$\hat{\mathbf{X}}^T \mathbf{A}^T \mathbf{a} = 337416.$$

Thus

$$\mathbf{a}^T \mathbf{a} - \hat{\mathbf{X}}^T \mathbf{A}^T \mathbf{a} = 338546 - 337416 = 1130,$$

and

$$s^2 = 1130/17 = 66 \cdot 5.$$

TABLE 3
OBSERVATIONAL MATRIX FOR $m = 5$

| A | | | | | | | | a Unit: 10^{-6} in. | Check | | | |
|------------------------------|----|----|----|----------------|----------------|----|---|---------------------------------|-------|--------------------|----|----|
| $\lambda_{(j-i)}$ $(j-i)$ | | | | X_k^i i | X_l^j j | 1 | 2 | | | | | |
| -4 | -3 | -2 | -1 | 0 | 1 | 2 | 3 | 4 | 1 | 2 | 3 | 4 |
| -1 | | | | | | -1 | | | -146 | = (0 - 146) | | -2 |
| -1 | | | | | | | 1 | | 29 | = (-31 + 60) | 0 | |
| | -1 | | | | | -1 | | | -146 | = (0 - 146) | -2 | |
| | -1 | | | | | -1 | 1 | | -39 | | -1 | |
| | -1 | | | | | | 1 | | 44 | = (-16 + 60) | 0 | |
| | -1 | | | | | -1 | | | -146 | = (0 - 146) | -2 | |
| | -1 | | | | | -1 | 1 | | -8 | | -1 | |

| | -1 | | | | | -1 | 1 | | -31 | | -1 | |
| | -1 | | | | | -1 | 1 | | -12 | | -1 | |
| | -1 | | | | | | 1 | | -170 | = (-20 - 210 + 60) | -1 | |
| | -1 | | | | | | 1 | | 0 | = (0 + 0) | 0 | |
| | -1 | | | | | -1 | 1 | | 39 | | -1 | |
| | -1 | | | | | -1 | 1 | | -39 | | -1 | |
| | -1 | | | | | -1 | 1 | | 43 | | -1 | |
| | -1 | | | | | | 1 | | -167 | = (43 - 210) | -2 | |
| | -1 | | | | | -1 | | | -16 | = (-16 + 0) | 0 | |
| | -1 | | | | | -1 | | | 8 | | -1 | |
| | -1 | | | | | -1 | | | -16 | | -1 | |
| | -1 | | | | | | 1 | | -198 | = (12 - 210) | -2 | |
| | -1 | | | | | | 1 | | -24 | = (-24 + 0) | 0 | |
| | -1 | | | | | -1 | | | 31 | | -1 | |
| | -1 | | | | | -1 | | | -249 | = (-39 - 210) | -2 | |
| | -1 | | | | | | 1 | | 0 | = (0 + 0) | 0 | |
| | -1 | | | | | -1 | | | -202 | = (8 - 210) | -2 | |

$$\mathbf{a}^T \mathbf{A} = [+117, +141, +54, -17, +509, +124, +222, +242, +202, +274, +560, +332, +324, -108, +12, +22, +153] . \text{ Check sum } +3163$$

$$\mathbf{a}^T \mathbf{a} = 146^2 + 29^2 + 146^2 + \dots + 202^2 = 338546$$

As in the case of simple calibration, the solutions for the X 's may be written in an alternative form.

Thus

$$\hat{X}_k^i = \hat{x}_k^i + \mathbf{X}_{kl}^T \mathbf{K}_i,$$

$$\hat{X}_l^j = \hat{x}_l^j + \mathbf{X}_{kl}^T \mathbf{L}_j,$$

where

$$\mathbf{K}_i = [3/4 - i/2m, 1/4 + i/2m, 1/4 - i/2m, -1/4 + i/2m]^T,$$

$$\mathbf{L}_j = [1/4 - j/2m, -1/4 + j/2m, 3/4 - j/2m, 1/4 + j/2m]^T,$$

$$\mathbf{X}_{kl}^T = [X_k^0, X_{k+1}^0, X_l^0, X_{l+1}^0],$$

and

$$\hat{\mathbf{x}} = (\mathbf{A}^T \mathbf{A})^{-1} \mathbf{A}^T \mathbf{b}.$$

We note that $\mathbf{X}_{kl} \mathbf{X}_{kl}^T$ is a 4×4 matrix and that the expectation of $(\mathbf{X}_{kl} - \bar{\mathbf{X}}_{kl})$, $(\mathbf{X}_{kl} - \bar{\mathbf{X}}_{kl})^T$, where

$$\bar{\mathbf{X}}_{kl}^T = [\bar{X}_k^0, \bar{X}_{k+1}^0, \bar{X}_l^0, \bar{X}_{l+1}^0]$$

is the variance-covariance matrix* of the vector \mathbf{X}_{kl} . For brevity the following notation is adopted

$$\Sigma_{kl} = \xi \{(\mathbf{X}_{kl} - \bar{\mathbf{X}}_{kl})(\mathbf{X}_{kl} - \bar{\mathbf{X}}_{kl})^T\}$$

$$= \begin{bmatrix} \sigma_{X_k^0}^2 & \sigma_{X_k^0 X_{k+1}^0} & \sigma_{X_k^0 X_l^0} & \sigma_{X_k^0 X_{l+1}^0} \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \sigma_{X_{l+1}^0}^2 \end{bmatrix},$$

$$\mathbf{K} = [\mathbf{K}_1, \mathbf{K}_2, \dots, \mathbf{K}_{m-1}],$$

the matrix whose column vectors are \mathbf{K}_i ,

$$\mathbf{L} = [\mathbf{L}_1, \mathbf{L}_2, \dots, \mathbf{L}_{m-1}],$$

the matrix whose column vectors are \mathbf{L}_j .

For a second cross calibration involving $X_a^0 X_{a+1}^0$, $X_\beta^0 X_{\beta+1}^0$ the matrices \mathbf{K} and \mathbf{L} will appear again but the vector \mathbf{X}_{ab} will replace \mathbf{X}_{kl} and Σ_{ab} will replace Σ_{kl} .

To establish the variances and covariances a number of separate cases must be distinguished corresponding to those enumerated under 2, 3, and 4 of Section II. The derivations of the relevant formulae in each of these cases follow essentially the same reasoning and so those corresponding to case 2(a) will be derived, the remainder merely being listed. Case 2(a) then corresponds to end-points falling within main divisions involved in the same cross calibrations and also falling within the left-hand main division.

* See footnote, p. 89.

We then have,

$$\begin{aligned}\text{Cov}(X_k^i, X_k^j) &= \xi \{(X_k^i - \bar{X}_k^i)(X_k^j - \bar{X}_k^j)\} \\ &= \xi \{(\{x_k^i + \mathbf{X}_{kl}^T \mathbf{K}_i\} - \{\bar{x}_k^i + \bar{\mathbf{X}}_{kl}^T \mathbf{K}_i\})(\{x_k^j + \mathbf{X}_{kl}^T \mathbf{K}_j\} - \{\bar{x}_k^j + \bar{\mathbf{X}}_{kl}^T \mathbf{K}_j\})\},\end{aligned}$$

leading to $\xi(\{x_k^i - \bar{x}_k^i\}\{x_k^j - \bar{x}_k^j\}) + \xi(\mathbf{K}_i^T (\mathbf{X}_{kl} - \bar{\mathbf{X}}_{kl}) (\mathbf{X}_{kl} - \bar{\mathbf{X}}_{kl})^T \mathbf{K}_j)$
since the x_k 's and the \mathbf{X}_{kl} 's are independent.

Hence finally

$$\text{Cov}(X_k^i, X_k^j) = \text{Cov}(x_k^i, x_k^j) + \mathbf{K}_i^T \mathbf{\Sigma}_{kl} \mathbf{K}_j, \quad i, j = 1, 2, \dots, m-1;$$

more concisely

$$[\text{Cov}(X_k^i, X_k^j)] = [\text{Cov}(x_k^i, x_k^j)] + \mathbf{K}^T \mathbf{\Sigma}_{kl} \mathbf{K},$$

where $[\text{Cov}(x_k^i, x_k^j)]$ is obtained from the inverse $(\mathbf{A}^T \mathbf{A})^{-1}$ on multiplication by the scalar σ^2 . (In practice the estimate of σ^2, s^2 , is used.)

A complete list is now given of covariances associated with a cross calibration.* In this list the only restriction on the superscripts i and j is that they should not equal 0 or m ; j may equal i .

1. Elements within the same cross calibrations:

(a) A length falling entirely within $X_k^0 X_{k+1}^0$,

$$[\text{Cov}(X_k^i, X_k^j)] = [\text{Cov}(x_k^i, x_k^j)] + \mathbf{K}^T \mathbf{\Sigma}_{kl} \mathbf{K}.$$

(b) A length falling entirely within $X_l^0 X_{l+1}^0$,

$$[\text{Cov}(X_l^i, X_l^j)] = [\text{Cov}(x_l^i, x_l^j)] + \mathbf{L}^T \mathbf{\Sigma}_{kl} \mathbf{L}.$$

(c) A length extending from a graduation in $X_k^0 X_{k+1}^0$ to a graduation in $X_l^0 X_{l+1}^0$,

$$[\text{Cov}(X_k^i, X_l^j)] = [\text{Cov}(x_k^i, x_l^j)] + \mathbf{K}^T \mathbf{\Sigma}_{kl} \mathbf{L}.$$

2. Elements within two different cross calibrations:

(a) A length extending from a graduation in the left-hand main division of a first cross calibration to a graduation in the left-hand main division of a second cross calibration. For a graduation in $X_k^0 X_{k+1}^0$ to a graduation in $X_a^0 X_{a+1}^0$

$$[\text{Cov}(X_k^i, X_a^j)] = \mathbf{K}^T [\text{Cov}(X_{kl}, X_{a\beta})] \mathbf{K},$$

where the expression on the right-hand side is a matrix of bilinear forms each involving the 4×4 matrix

$$[\text{Cov}(X_{kl}, X_{a\beta})] = \begin{bmatrix} \sigma_{X_k^0 X_a^0} & \sigma_{X_k^0 X_{a+1}^0} & \sigma_{X_k^0 X_\beta^0} & \sigma_{X_k^0 X_{\beta+1}^0} \\ \sigma_{X_{k+1}^0 X_a^0} & \sigma_{X_{k+1}^0 X_{a+1}^0} & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \sigma_{X_{l+1}^0 X_{\beta+1}^0} \end{bmatrix}.$$

* The cases here numbered 1–3 are cases 2–4 of Section II. (Case 1 of Section II involved only simple calibrations.)

- (b) A length extending from a graduation in the right-hand main division of a first cross calibration to a graduation in the right-hand main division of a second cross calibration. For a graduation in $X_l^0 X_{l+1}^0$ to a graduation in $X_\beta^0 X_{\beta+1}^0$,

$$[\text{Cov } (X_l^i, X_\beta^j)] = \mathbf{L}^T [\text{Cov } X_{kl}, X_{a\beta}] \mathbf{L}.$$

- (c) A length extending from a graduation in the right-hand main division of a first cross calibration to a graduation in the left-hand main division of a second cross calibration. For a graduation in $X_l^0 X_{l+1}^0$ to a graduation in $X_a^0 X_{a+1}^0$,

$$[\text{Cov } (X_l^i, X_a^j)] = \mathbf{L}^T [\text{Cov } (X_{kl}, X_{a\beta})] \mathbf{K}.$$

- (d) A length extending from a graduation in the left-hand main division of a first cross calibration to a graduation in the right-hand main division of a second cross calibration. For a graduation in $X_k^0 X_{k+1}^0$ to a graduation in $X_\beta^0 X_{\beta+1}^0$,

$$[\text{Cov } (X_k^i, X_\beta^j)] = \mathbf{K}^T [\text{Cov } (X_{kl}, X_{a\beta})] \mathbf{L}.$$

3. Main graduation to subdivisional graduation:

- (a) A length extending from a main graduation to a left-hand subdivisional graduation of a cross calibration,

$$\text{Cov } (X_t^0, X_k^i) = [\sigma_{X_t^0 X_k^0}, \sigma_{X_t^0 X_{k+1}^0}, \sigma_{X_t^0 X_l^0}, \sigma_{X_t^0 X_{l+1}^0}] \mathbf{K}_i,$$

where t may assume any of the integral values 0 to n .

- (b) A length extending from a main graduation to a right-hand subdivisional graduation of a cross calibration,

$$\text{Cov } (X_t^0, X_l^i) = [\sigma_{X_t^0 X_k^0}, \sigma_{X_t^0 X_{k+1}^0}, \sigma_{X_t^0 X_l^0}, \sigma_{X_t^0 X_{l+1}^0}] \mathbf{L}_i,$$

where again t may assume any of the integral values 0 to n .

It is not suggested that it would be profitable to calculate the entire variance-covariance matrix in every case but rather that the values be calculated as they are required. As an example of these calculations the values corresponding to $[\text{Cov } (X_0^i, X_2^j)]$ in the previous example will be calculated (case 1(c) in the above list).

The elements corresponding to $[\text{Cov } (x_0^i, x_2^j)]$ are obtained from the appropriate elements of the inverse $(\mathbf{A}^T \mathbf{A})^{-1}$ for the cross calibration on multiplication by $s^2 = 66.5$, i.e.

$$(66.5/2160) \begin{bmatrix} 4 & -37 & -73 & -104 \\ -37 & -74 & -101 & -73 \\ -73 & -101 & -74 & -37 \\ -104 & -73 & -37 & 4 \end{bmatrix} = \begin{bmatrix} 0 & -1 & -2 & -3 \\ -1 & -2 & -3 & -2 \\ -2 & -3 & -2 & -1 \\ -3 & -2 & -1 & 0 \end{bmatrix}$$

on rounding.

To this 4×4 matrix is added the matrix

$$\mathbf{K}^T \Sigma_{kl} \mathbf{L}$$

Now

$$\mathbf{K}^T = \begin{bmatrix} 0.65 & 0.35 & 0.15 & -0.15 \\ 0.55 & 0.45 & 0.05 & -0.05 \\ 0.45 & 0.55 & -0.05 & 0.05 \\ 0.35 & 0.65 & -0.15 & 0.15 \end{bmatrix},$$

$$\mathbf{L} = \begin{bmatrix} 0.15 & 0.05 & -0.05 & -0.15 \\ -0.15 & -0.05 & 0.05 & 0.15 \\ 0.65 & 0.55 & 0.45 & 0.35 \\ 0.35 & 0.45 & 0.55 & 0.65 \end{bmatrix},$$

and from the simple calibration

$$\Sigma_{kl} = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 0 & 15 & 17 & 23 \\ 0 & 17 & 36 & 46 \\ 0 & 23 & 46 & 74 \end{bmatrix}.$$

Multiplication then gives on rounding,

$$\mathbf{K}^T \Sigma_{kl} \mathbf{L} = \begin{bmatrix} 3 & 4 & 4 & 5 \\ 7 & 8 & 8 & 9 \\ 10 & 11 & 13 & 14 \\ 13 & 15 & 17 & 19 \end{bmatrix},$$

leading finally to

$$[\text{Cov } (X_0^i, X_2^j)] = \begin{bmatrix} (i) & (j) \\ 3 & 3 & 2 & 2 \\ 6 & 6 & 5 & 7 \\ 8 & 8 & 11 & 13 \\ 10 & 13 & 16 & 19 \end{bmatrix},$$

where the unit is 10^{-12} in^2 .

V. CONCLUSION

The analysis given here is applicable not only to the treatment of the subdivision of linear scales but also to any series of observations which conforms to the pattern and has the same dependencies. For the simple calibration scheme of circular scales or polygons the analysis of Cook (1954) is appropriate. When, however, it is necessary to use a cross calibration in the circular case the analysis given here should be applied.

VI. ACKNOWLEDGMENTS

The values of the inverse matrices were obtained by use of the University of Sydney's automatic computer (SILLIAC). The assistance in the computations of Mrs. Mary Tonkin, Mrs. Rosemary Munsie, Miss Betty Buck, and Mr. K. D. Heeley is gratefully acknowledged.

APPENDICES

$$(\mathbf{A}^T \mathbf{A})^{-1}$$

Inverse of the Matrix of the Normal Equations

Elements of the inverses are given as integral multiples of their actual values; the appropriate divisor d is given with each table. The row “column sums” has been added to facilitate a check on the arithmetic.

For the purpose of reproduction it has been necessary to partition some of the larger matrices. Where the partitioning has been made into two submatrices the division has been made so that one matrix, Λ , is associated with the λ 's and the other, \mathbf{X} , with the X 's. In the case of the 37×37 matrix it has been necessary to partition into four submatrices. In this case, Λ_1 and Λ_2 are associated with the λ 's and \mathbf{X}_1 and \mathbf{X}_2 with the X 's.

APPENDIX I

Simple Calibration, Tables 1.1 to 1.6

The number of main divisions is n ; the number of λ 's is $(n-1)$ and the number of X 's is $(n-1)$.

APPENDIX II

Cross Calibration, Tables 2.1 to 2.4

The number of subdivisions in a main division is m ; the number of λ 's is $(2m-1)$ and the number of X 's is $2(m-1)$.
