**Table S2: Analysis of eucalypt bark allometry.**

We present species x locality records here because bark thickness is a highly labile trait depending on fire intensity at a locality. We used log-log functions ( $BT = \exp(k + \alpha \cdot \log(DBH))$ ) and segmented regression to detect breakpoints.  $R^2$  is the coefficient of determination. Regression coefficients and their fit are given for all data and data up to the breakpoint (first segment) and beyond the breakpoint (second segment). NaN, Not available – in most instances because there were too few data to calculate a meaningful  $P$ -value.
