1) Computational approach for calculating solvation free energies

To further validate our computational approach, we calculated and analyzed solvation free energies for Pb²⁺. Solvation free energies are defined as the free energy change that occurs when a solute is taken from the gas phase into the solvent^[1,2]; in the context of this study, the solvation free energy is the free energy change associated with the following reaction:

This approach for calculating the solvation free energy is well-established in the literature.^[2,3]

The Gibbs free energy change of the reaction is calculated using the thermodynamic cycle thoroughly discussed in the Computational Details of the main text. To summarise this cycle, the energy of the reactants is subtracted from the energy of the products, where the free energy of the species in aqueous solution (*i.e.*, $\text{H}_2\text{O}_{(\text{aq})}$ and $\text{Pb}(\text{H}_2\text{O})_n^{2+}_{(\text{aq})}$) is calculated using the following equation:

$$G_{\text{solv}} = E^{\text{B2}}_{\text{gas}} + (G^{\text{B1}}_{\text{gas}} - E^{\text{B1}}_{\text{gas}}) + (E^{\text{B2}}_{\text{solv}} - E^{\text{B2}}_{\text{gas}}) + \Delta G^{0 \rightarrow *} \quad (\text{S2})$$

Where G_{solv} is the final solvated Gibbs free energy; E is the electronic energy; G is the Gibbs free energy; B1 indicates whether the calculation was conducted with the basis set used for optimizations and frequency calculations (for this sub-study, either aug-cc-pVDZ on H and O, aug-cc-pVDZ-PP with the Stuttgart-Koeln small-core multiconfiguration-Dirac-Hartree-Fock-adjusted (SK MCDHF RSC) ECP on Pb^[4-7] or def2-SVP on H and O. def2-TZVPP with the def2-ECP on Pb^[7-9]) and B2 indicates the basis set used for single point refinements (either aug-cc-pVDZ on H and O, aug-cc-pVDZ-PP with the SK MCDHF RSC ECP on Pb or ma-def2-TZVP on H and O, ma-def2-TZVPP with the def2- ECP on Pb); the gas and solv subscripts designate whether the calculation was conducted in gas phase or with implicit solvation, and $\Delta G^{0 \rightarrow *}$ is the concentration correction applied as described by Keith *et al.*^[10] The free energy of $\text{Pb}^{2+}_{(\text{g})}$ was calculated as follows, as solvation corrections are not required for species in gas phase:

$$G_{\text{Pb}^{2+}} = E^{\text{B2}}_{\text{gas}} + (G^{\text{B1}}_{\text{gas}} - E^{\text{B1}}_{\text{gas}}) \quad (\text{S3})$$

2) Effect of coordination number on Pb^{2+} solvation free energies

As thoroughly examined in the main text, a key aspect of modelling solvated Pb^{2+} is determining the most suitable coordination number and we found that a coordination number

of six leads to the best agreement with experiments in terms of geometry (discussion of Fig. 2 in the main text and section 3 of the Supplementary Material). Here we further examine this aspect by calculating the solvation free energy for Pb^{2+} across coordination numbers ranging from six to nine (Table S1). In addition to our analysis of the coordination number, we also tested modifying the size of the water cluster used to model the solvating water molecules in solution on the reactant side in Eqn. S1. We tested modelling these water molecules using two approaches. The first involves Pb^{2+} interacting with n non-interacting water molecules (*i.e.*, $n \text{H}_2\text{O}$, or the monomer approach). The second method involves modelling each water molecule as an ‘average’ water molecule taken from a larger cluster of m interacting water molecules (*i.e.*, $n/m \text{mH}_2\text{O}$, also known as the cluster model approach). We tested clusters made of $m=6$ water molecules (*i.e.*, a hexamer cluster) and $m=9$ (*i.e.*, a nonamer cluster). While the effect of coordination number on solvation free energies is minimal (*e.g.*, <1 kcal/mol difference in solvation free energy for coordination numbers six to eight when modelling solvating waters with hexamer and nonamer clusters), $\text{Pb}(\text{H}_2\text{O})_6^{2+}$ leads to the most accurate solvation free energy thus providing further justification for choosing this coordination number and geometry to model solvated Pb^{2+} .

There is a significant difference in solvation free energies on the order of approximately 20 kcal/mol when transitioning from a monomer approach to a water cluster model (-337.3 kcal for $\text{Pb}(\text{H}_2\text{O})_7^{2+}$ calculated using the monomer *vs.* 357.3 kcal/mol for hexamer). While this trend may appear to suggest that the monomer is the best description of liquid water, this is a spurious result driven by our chosen model chemistry which may be overestimating solvation free energies relative to the experimental value (see section 5 of the Supplementary Material). Modelling water as a monomer provides less thermodynamic driving force for solvation of Pb^{2+} to occur, hence leading to less negative solvation free energies. Therefore, we chose to use the nonamer cluster to accurately describe bulk water, in agreement with previous literature

that indicates that the water cluster approach should be used for solvation free energy calculations for charged solutes.^[11] The difference between hexamer and nonamer water clusters is much smaller (approximately 5 kcal/mol), indicating that either could potentially be used for calculating Pb²⁺ solvation energies.

Table S1. A comparison of solvation free energies with different water cluster sizes across coordination numbers 6-9. The sequential water addition energy is also presented, calculated as the energy produced by the Pb(H₂O)_{n-1}²⁺ + H₂O → Pb(H₂O)_n²⁺ reaction. All energies are calculated using the ωB97X-D3BJ/def2-SVP/ma-def2-TZVP (def2-TZVPP/ma-def2-TZVPP on Zr, Pb) model chemistry.

Coordination number	Solvation free energy (monomer)	Solvation free energy (hexamer)	Solvation free energy (nonamer)	Sequential water addition energy (kcal/mol)
6	-339.0	-356.1	-353.2	-2.2
7	-337.3	-357.3	-353.8	-1.5
8	-334.6	-357.4	-353.5	2.6
9	-334.9	-360.6	-356.2	-3.6

3) Geometries of Pb(H₂O)_n²⁺ (n=6-9)

We report the geometries of Pb(H₂O)_n²⁺ (n=6-9) in order to demonstrate the transition between hemidirectionality to holodirectionality as the coordination number increases (Fig. S1). We focus on these four coordination geometries because, as demonstrated in the main text (Fig. 2), they are all thermodynamically accessible at room temperature. Pb(H₂O)_n²⁺ with n=6,7 is hemidirected while Pb(H₂O)_n²⁺ n=8,9 is holodirected. All geometries are optimized using the ωB97X-D3BJ/def2-SVP (def2-TZVPP with def2- ECP on Pb) model chemistry.^[7-9,12,13] As discussed in the main text, the average Pb-O bond length increases with coordination number: 2.55 Å for Pb(H₂O)₆²⁺, 2.62 Å for Pb(H₂O)₇²⁺ with, 2.66 Å for Pb(H₂O)₈²⁺, and 2.70 Å for Pb(H₂O)₉²⁺. The average bond length obtained with Pb(H₂O)₆²⁺ is the most consistent with the experimental value of 2.54 Å.^[14]

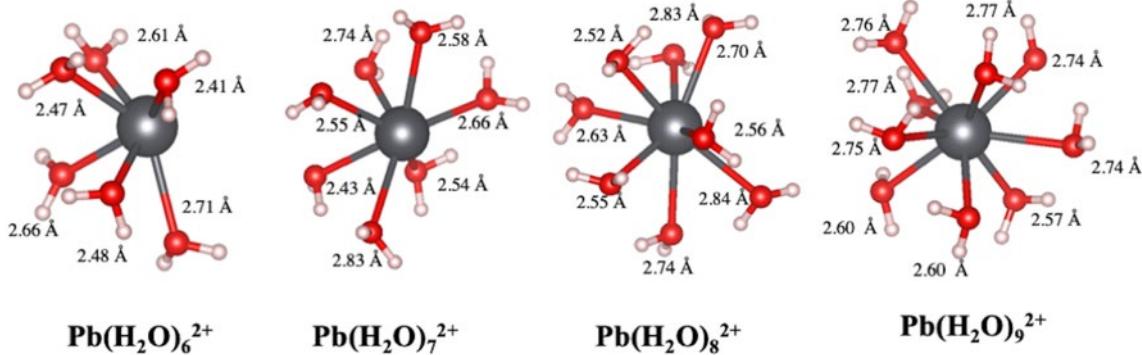

Figure S1. Visual depictions of the $\text{Pb}(\text{H}_2\text{O})_n^{2+}$ ($n=6$ to 9) geometries along with all Pb-O bond lengths in Angstroms for each species. $\text{Pb}(\text{H}_2\text{O})_n^{2+}$ ($n=6$ to 7) is hemidirected; $\text{Pb}(\text{H}_2\text{O})_n^{2+}$ ($n=8$ to 9) is holodirected. Pb atoms in grey, O in red, H in off-white.

4) Energetics of adsorption for fully desolvated Pb^{2+}

As discussed in the Results and Discussion section of the main text, it is plausible that Pb^{2+} could desolvate passing through the UiO-66 triangular apertures. This would have a significant effect on ΔG_s and hence also on the adsorption capacity of functionalised UiO-66. This prompted us to calculate the ΔG_s for the bare Pb^{2+} ion adsorbing onto functionalised linkers with no explicit solvation (Fig. S2) as an extreme case for the desolvation possibly induced by the small apertures in the UiO-66 structure. This analysis also allowed us to further validate our computational method in terms of testing whether it correctly captures the chemistry of Pb^{2+} interaction with different Lewis bases, without the confounding factors of ligand exchange thermodynamics (Fig. 4 in the main text) and the presence of water molecules affecting the electrophilicity of Pb^{2+} (Fig. 5 in the main text).

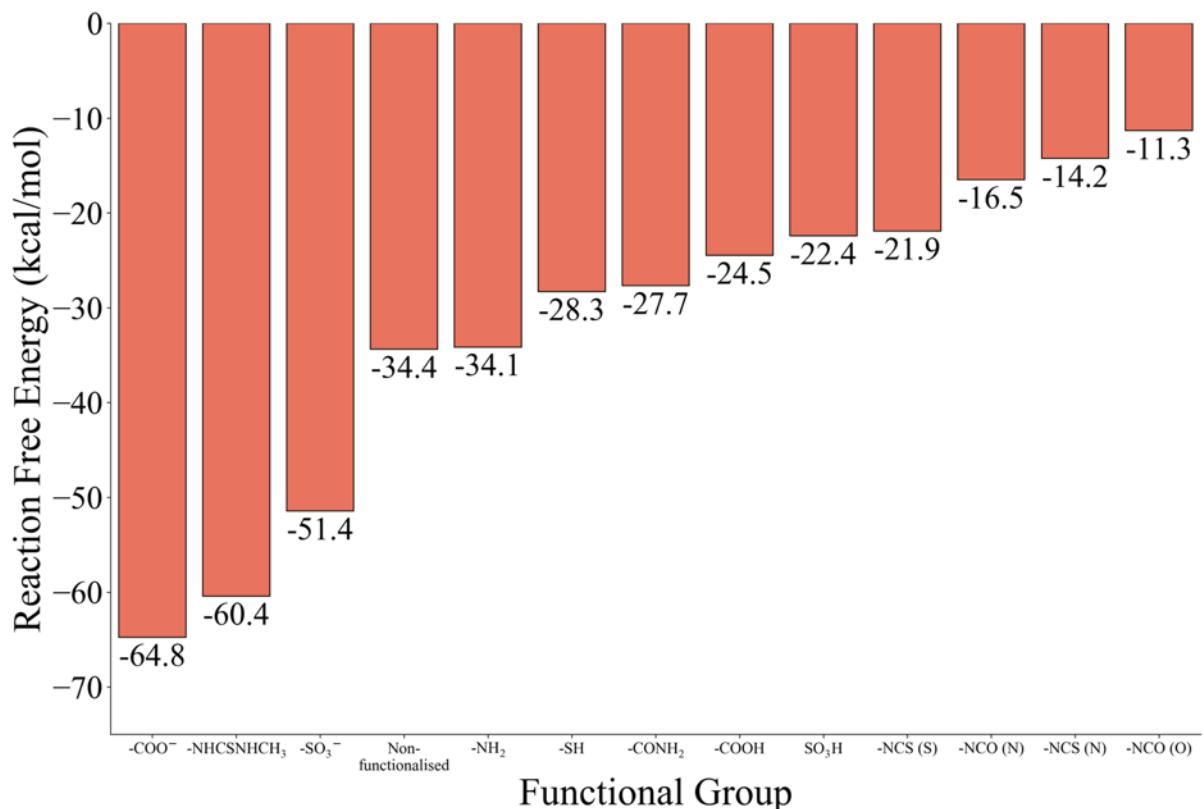

Figure S2. Comparison of the reaction free energy (ΔG) in kcal/mol of the lone Pb^{2+} ion binding onto different adsorption sites on functionalised linkers (labelled according to the functional group for brevity) with no water molecules present. The reaction plotted is $Pb^{2+} + L^n \rightarrow L-Pb^{n+2}$ where L is the functionalised MOF and $n=0$ for all ligands except COO^- and SO_3^- where $n=-1$. For the - NCS and - NCO functionalised MOFs, the atom in brackets is the adsorption site where Pb^{2+} is bound.

Unlike the reaction depicted in Fig. 4 of the main text which is an exchange reaction between water and the functionalised linkers, the reaction in Fig. S2 is direct adsorption of fully desolvated Pb^{2+} with no loss or gain of water molecules (comparable to Fig. 5 in the main text, which examines adsorption of partially desolvated Pb^{2+}). As described in the main text, the notation for functionalised UiO-66 is simply the functional group that acts as the adsorption site (*i.e.*, UiO-66-SH is reported as -SH). Not surprisingly, the ΔG s are all consistently and significantly more favourable relative to those found when modelling solvated Pb^{2+} adsorption using explicit water molecules but the overall adsorption trend remain similar. Charged (-COO⁻, -SO₃⁻) and chelating (-COO⁻, -NHCSNHCH₃) species are still the most favourable, with the ΔG of Pb^{2+} adsorbing onto -COO⁻ equal to -64.8 kcal/mol (in close agreement with density functional theory calculations conducted by Zhao *et al.*^[15]). However, we observe that the -SH functional group now demonstrates more favourable ΔG s compared to the -CONH₂ functional

group once all explicit water molecules are removed. Note that in the absence of the explicit solvation shell the coordination geometry spontaneously optimised to a chelating geometry for both of these functional groups. The significant steric strain caused by the proximity of the two functional groups in -CONH₂ leads to this adsorption configuration being less favourable than -SH. In addition to these trends, we found that we were able to stabilize a greater variety of geometries during the optimization process in the absence of explicit water molecules. In particular, we successfully optimized geometries with Pb²⁺ bound to the nitrogen atom rather than the terminal oxygen and sulphur atoms for the -NCO and -NCS ligands, respectively. The steric bulk introduced when incorporating a partial or full solvation shell clearly prevents adsorption on less accessible binding sites. This suggests that if Pb²⁺ is partially or fully desolvated as it passes through the triangular aperture, it could potentially interact with more sites on functionalised linkers.

5) Effect of water cluster size and model chemistry on Pb²⁺ solvation free energies

In the main text we thoroughly discussed our choice of model chemistry and coordination number for solvated Pb²⁺ based on consistency with experimental findings reporting a hemidirected geometry with bond lengths comparable to our Pb(H₂O)₆²⁺ simulated complex. Another way to validate our computational method is by comparing computed solvation free energies to the experimental literature. In addition to the water cluster size, we considered the functional and basis set used for the calculations.

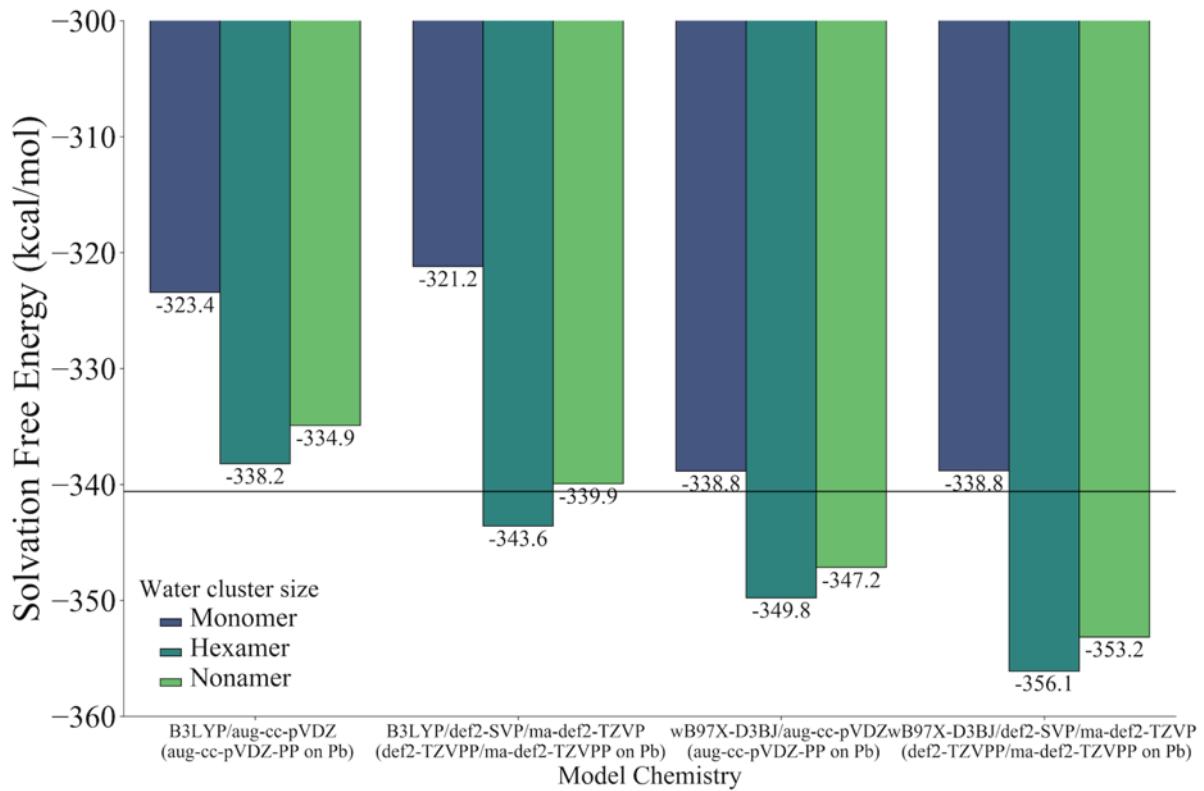

Figure S3. Comparison of Pb^{2+} solvation free energy computed using different combinations of two functionals (B3LYP and $\omega\text{B97X-D3BJ}$) and two basis set (aug-cc-pVDZ (aug-cc-pVDZ-PP on Pb) and $\text{def2-SVP/ma-def2-TZVP}$ ($\text{def2-TZVPP/ma-def2-TZVPP}$ on Pb)). Solvation free energies were calculated according to Eqn. S1 and by modelling six explicit water molecules coordinating solvated Pb^{2+} . Three water cluster sizes are considered to model the solvent molecules: a monomer, a hexamer, and a nonamer. The experimental solvation free energy of the Pb^{2+} ion (-340.6 kcal/mol)^[16] is depicted as a black line.

We calculated the solvation free energy according to Eqn. S1 with $n=6$ (*i.e.*, modelling $\text{Pb}^{2+}_{(\text{g})}$ + $6\text{H}_2\text{O}_{(\text{aq})} \rightarrow \text{Pb}(\text{H}_2\text{O})_6^{2+}_{(\text{aq})}$) using four combinations of functionals (B3LYP ^[17] and $\omega\text{B97X-D3BJ}$ ^[12,13]) and basis sets (aug-cc-pVDZ (aug-cc-pVDZ-PP with the SK MCDHF RSC ECP on Pb)^[5-7,18] and $\text{def2-SVP/ma-def2-TZVP}$ ($\text{def2-TZVPP/ma-def2-TZVPP}$ with the def2-ECP on Pb)^[7-9]) (Fig. S3). Of all possible combinations of basis sets and functionals presented in Table 1 in the main text, here we focus on these four combinations based on previous literature. Both selected functionals had previously been used for modelling Pb^{2+} solvation shells;^[2,3] the basis sets were chosen either because they have been recommended in the literature for Pb^{2+} hydration (in the case of aug-cc-pVDZ (aug-cc-pVDZ-PP with the SK MCDHF RSC ECP on Pb))^[2,3] or because they have been used previously by us to model heavy metal adsorption on UiO-66 ($\text{def2-SVP/ma-def2-TZVP}$ ($\text{def2-TZVPP/ma-def2-TZVPP}$ with the def2-ECP on

Pb)).^[19] B3LYP generates solvation free energies less negative than ω B97X-D3BJ across all basis sets and water cluster sizes, with the B3LYP/def2-SVP/ma-def2-TZVP (def2-TZVPP/ma-def2-TZVPP with the def2- ECP on Pb) model chemistry producing the closest solvation free energy to experimental values (-339.9 kcal/mol calculated vs. -340.6 kcal/mol experimental^[16]). However, as previously noted, the use of B3LYP always leads to holodirected geometries (Table 1 in the main text and related discussion) that are in disagreement with the experimental literature,^[14] and hence this functional is not a good choice to accurately model solvated Pb^{2+} . The basis set effect on the computed solvation free energy is less significant compared to the functional effect. We do observe however that the aug-cc-pVDZ basis set consistently produces solvation free energies less negative than the def2 series of basis sets and closer to the experimental value. Overall, the trends indicate that our chosen model chemistry (ω B97X-D3BJ/def2-SVP/ma-def2-TZVP (def2-TZVPP/ma-def2-TZVPP with the def2- ECP on Zr, Pb)) could potentially slightly overestimate solvation free energies. However, solvation free energies are only one way to benchmark a model chemistry and our chosen computational method is backed by numerous benchmark studies reported in the main text and in the literature.^[20-22] Furthermore, this is the same method we used in our previous study in which we developed a cluster model for the UiO-66 nodes, which we employ in the current study to model Pb^{2+} interaction with defect sites.^[19]

The size of the water cluster also has a non-negligible effect on the computed solvation free energies (Fig. S3), with the ordering of accuracy relative to the experimental value (-340.6 kcal/mol) being the monomer (-338.8 kcal/mol), followed by the nonamer (-353.2 kcal/mol) and hexamer (-356.1 kcal/mol) when using our selected model chemistry. As discussed previously, this is an artifact of our model chemistry overestimating solvation free energies relative to the experimental value combined with the fact that the monomer provides less thermodynamic driving force for solvation of Pb^{2+} to occur. Given that the choice of functional

and basis set plays a significant role (as demonstrated by Fig. S3), the use of a larger water cluster such as a nonamer to describe free water remains the most suitable choice. This choice is also consistent with our previous study on As(V) adsorption by UiO-66.^[19]

6) Effect of adsorbed Pb²⁺ coordination number and water cluster size on reaction free energies

We assessed the effect of the coordination number of adsorbed Pb²⁺ and the water cluster size on the reaction free energies (ΔG_s) by using the adsorption of Pb(H₂O)₆²⁺ onto UiO-66-NH₂ as a case study. We chose this adsorption site as it was the most stable adsorption site on functionalised linkers without confounding factors such as chelation (where higher coordination numbers could impose steric strain on the structure) or electrostatic attraction (as the Pb²⁺ cation becomes less electrophilic when coordinated by additional water molecules). This analysis was done on two types of reactions: the exchange of a water molecule with a functionalised linker (*i.e.*, Pb²⁺ coordination number constant and equal to six across the reaction) and direct adsorption with no loss or gain of free water molecules (*i.e.*, final coordination number seven). The reaction with a final coordination number of seven is more favourable than six, likely since Pb²⁺ is not forced to lose a coordinated water molecule and is stabilized by the increased number of bonds; this agrees with our observation in Fig. 2 that Pb(H₂O)₇²⁺ is the most stable solvated Pb²⁺ species. That said, the ΔG differences between coordination numbers are very small (2.3 kcal/mol at most), hence both final complexes are likely thermodynamically accessible at room temperature. With regards to the water cluster size, the ΔG differences are mostly negligible (less than 2 kcal/mol with the largest difference being between the monomer and the hexamer). This further corroborates our choice for modelling solvating water using a nonamer cluster as it shows that our predicted ΔG_s for Pb²⁺ adsorption are not dramatically affected by the choice of water cluster size.

Table S2. Comparison of the reaction free energy (ΔG) in kcal/mol for the $Pb(H_2O)_6^{2+}$ complex adsorbing onto $UiO-66-NH_2$ with different final coordination numbers and different water cluster sizes used to model the product water molecule. The reaction considered is $Pb(H_2O)_6^{2+} + UiO-66-NH_2 \rightarrow UiO-66-NH_2-Pb(H_2O)_a^{2+} + bH_2O$, where a is the final coordination number -1, and $b=0$ for final coordination number 7 and 1 for final coordination number 6. Note that the ΔG for coordination number 7 is identical across water cluster size as there are no water molecules involved in the reaction.

Final coordination number	Final species	Monomer	Hexamer	Nonamer
6	$UiO-66-NH_2-Pb(H_2O)_5^{2+}$	5.3	6.9	6.4
7	$UiO-66-NH_2-Pb(H_2O)_6^{2+}$	4.6	4.6	4.6

7) Cartesian coordinates of gas-phase optimized structures

For the reader's convenience, the geometries are organised according to the figure in which data based on each geometry is first presented. If the model chemistry was not specified, the model chemistry used for the geometry optimization was ω B97X-D3BJ /def2-SVP (def2-TZVPP with def2- ECP on Pb).
