The period over which temperatures were averaged

Octopuses in each survey vary in age from young to older (larger), so that the temperatures over the full possible life span affect the survey result, particularly if the temperature effect is a result of differential survival at early life stages as surmised.

Here, we present an exploration of the impact that the period over which temperatures were averaged has on the correlation of temperatures with octopus abundance. Shifting the two ends of the period over which temperature is averaged necessarily cuts out the most recent past (affecting very small octopuses) or the more distant past (affecting larger octopuses).

Nonetheless, we tested these factors again for the REEF data (Washington State waters) by calculating average temperatures over 12 different periods, including all combinations from 1 to 5 years before only 1 year prior, 2–5 years before only 2nd year prior and 3–5 to only 3rd year prior. We examined the correlation of the changing start time (Fig. S1, top left), end time (Fig. S1, top right) and total number of average years (Fig. S1, bottom) on the R^2 relationship.

The resulting correlations of average temperatures to WA octopus sighting frequencies ranged from $R^2 = 0.27$ (only 1 year prior in temperature average) to 0.83 (only 2–3 years prior).

This re-analysis found that (1) there was no effect on R^2 of changing the starting lag (the most recent prior year included in the average); (2) the correlation increases if more than 1 year is averaged, but once 3 years are included, there is no further improvement in the R^2 values; and (3) the correlation increases with end years prior from 1 to 3 years but reaches a plateau at 3–5 years.

From this, we reaffirm our understanding and that of Scheel (2015) that (1) it is not the very recent past temperatures alone that are strongly correlated with the octopus sighting frequency, (2) nor is it the temperature during each octopus's entire life span that affects the octopus sighting frequency. Instead, (3) over a time frame of approximately the life span of the sample of sighted animals, the earliest temperatures have the strongest

correlations with the octopus sighting frequency. Because each sighting frequency includes animals of different ages, the average over the prior 4 years (larger animals, WA) or 2.5 years (smaller animals, AK) is reasonable and biologically realistic to examine.

Publicly available data

Sources are listed in the manuscript for publicly available datasets used for PDO, northern Pacific sea-surface temperatures, and Washington State historical water temperatures, and the REEF datasets. The annual REEF sighting frequency values used in the paper can also be reproduced as described by using interactive reports on the reef.org website. Although the raw REEF data contain additional interesting variables accessible by contacting Reef's science director, analyses presented in this paper do not rely on these additional variables. REEF uses this process to track usage, but they provide raw data extracts to any interested researchers who request it.

Table S1. PWS surveys – Prince William Sound survey data headers

Date, date of octopus survey; site description, narrative description of survey location; Occ, number of occupied octopus dens; Area, area of survey (m²); year, year of survey; number, alphanumeric designator of survey site; density, number of occupied octopus dens per 1000 m² surveyed area
